A Note on Sampling and Parameter Estimation in Linear Stochastic Systems

T. E. Duncan, P. Mandl, and B. Pasik-Duncan

Abstract— Numerical differentiation formulas that yield consistent least squares parameter estimates from sampled observations of linear, time invariant higher order systems have been introduced previously by Duncan et al. The formulas given by Duncan et al. have the same limiting system of equations as in the continuous time case. The formula presented in this note can be characterized as preserving asymptotically a partial integration rule. It leads to limiting equations for the parameter estimates that are different from the continuous case, but they again imply consistency. The numerical differentiation formulas given here can be used for an arbitrary linear system, which is not the case in the previous paper by Duncan et al.

Index Terms—Estimation, linear stochastic systems, numerical differentiation for stochastic systems, sampling.

I. INTRODUCTION

In a previous paper by the authors [2], the following parameter estimation problem in linear stochastic differential equations is considered. Let $\mathbf{X}(t)$, $t \geq 0$, be an $n$-dimensional process satisfying

$$d\mathbf{X}^{(i-1)}(t) = \left( \sum_{i=1}^{d} f_i(\alpha) \mathbf{X}^{(i-1)}(t) + g(\alpha)U(t) \right) dt + dW(t)$$

(1)

where

$$\mathbf{X}^{(i)}(t) = \frac{d}{dt} \mathbf{X}^{(i-1)}(t), \quad i = 1, 2, \ldots, d-1$$

$$\mathbf{X}^{(0)}(t) = \mathbf{X}(t)$$

(2)

where $(U(t), t \geq 0)$ is a nonanticipative input process, $(W(t), t \geq 0)$ is an $n$-dimensional Wiener process with the local variance matrix $h$, $\alpha = (\alpha^1, \ldots, \alpha^p)$ is a $p$-dimensional unknown parameter

$$f_i(\alpha) = f_0 + \sum_{j=1}^{p} \alpha^j f_{ij}, \quad g(\alpha) = g_0 + \sum_{j=1}^{p} \alpha^j g_j.$$

In these descriptions, $f_{ij}, g_j$ for $i, j = 0, \ldots, p$ are known matrices. The true value of the unknown parameter is denoted by $\alpha_0 = (\alpha_0^1, \ldots, \alpha_0^p)$.

The least squares estimation of $\alpha_0$ from the observation of $(\mathbf{X}_t, U_t, \quad t \in [0, T])$

is determined by minimizing the formal quadratic functional

$$\int_0^T \left[ \left( \mathbf{X}^{(d)} - \sum_{i=1}^{d} f_i(\alpha) \mathbf{X}^{(i-1)} - g(\alpha)U \right)^T \right] dt \times L \left[ \mathbf{X}^{(d)} - \sum_{i=1}^{d} f_i(\alpha) \mathbf{X}^{(i-1)} - g(\alpha)U \right] - \mathbf{X}^{(d)} L \mathbf{X}^{(d)} dt$$

Publisher Item Identifier S 0018-9286(99)08614-6.
where $L$ is a positive semidefinite matrix. Prime denotes the transposition of vectors and matrices. The undefined term $X^{(i)} L X^{(j)}$ is cancelled, and $X^{(i)} dt = dX^{(i-1)}$ in (3).

By minimizing (3), the following family of equations for the least squares estimate $\alpha^*(T) = (\alpha^*(T), \cdots, \alpha^*(T))$ of $\alpha_0$ is obtained:

$$
\sum_{k=1}^n \frac{1}{T} \int_0^T \left( \sum_{i=1}^d f_{ij} X^{(i-1)} + g_i U \right) dt \alpha^{*k}(T) \\
\times L \left( \sum_{k=1}^n f_{jk} X^{(k-1)} + g_j U \right) dt \alpha^{*k}(T)
$$

$$
= \frac{1}{T} \int_0^T \left( \sum_{i=1}^d f_{ij} X^{(i-1)} + g_i U \right) dt
$$

$$
\times L \left( \sum_{k=1}^n f_{jk} X^{(k-1)} + g_j U \right) dt
$$

$$
= \frac{1}{T} \int_0^T \left( \sum_{i=1}^d f_{ij} X^{(i-1)} + g_i U \right) dt
$$

$$
\times L \left( \sum_{k=1}^n f_{jk} X^{(k-1)} + g_j U \right) dt
$$

$$
\quad j = 1, \cdots, d.
$$

(4)

It is assumed in [2] that discrete observations of $\{X(t), t \in [0, T]\}$ and $\{U(t), t \in [0, T]\}$ with uniform sampling interval $\delta > 0$ are only available yielding the observed random variables

$$
X_{m, \delta} = X(m \delta),
$$

$$
U_{m, \delta} = U(m \delta), \quad m = 0, \cdots, N + n.
$$

The notation $U$ is used to include the case when the product $g(\alpha) U(t)$ depends only on some coordinates of $U$. It is assumed that all of these coordinates are observed.

To approximate (4) using only random variables in (5), a substitution for the derivatives $X^{(i)}(m \delta)$ by the forward differences

$$
D^i X_{m, \delta} = \left( D^{i-1} X_{m+1, \delta} - D^{i-1} X_{m, \delta} \right) / \delta.
$$

$$
i = 1, 2, \cdots, d - 1
$$

is performed and some numerical integration formulas are used to evaluate the integrals. Denoting by

$$
\hat{\alpha}_{N \delta} = (\hat{\alpha}_{N \delta}^1, \cdots, \hat{\alpha}_{N \delta}^p)
$$

the estimate so obtained by these substitutions it is desirable that the consistency property

$$
\lim_{b \to 0} \lim_{N \to \infty} \hat{\alpha}_{N \delta} = \alpha_0
$$

is satisfied. In this expression $\lim_{N \to \infty} \hat{\alpha}_{N \delta}$ denotes the limit in probability, which under appropriate hypotheses is a nonrandom quantity.

In [4] and [6] it is noted that the forward and backward Euler approximations cannot be used, but it is shown how to modify the approximation for the highest derivative to satisfy (7). In [6] a specific approximation of the delta operator is given for the sampled data. It is shown in [1] for $n = 2$ and in [2] for $n \geq 2$ that (7) does not hold unless a correction term is introduced into the equations for $\hat{\alpha}_{N \delta}$ or unless (6) is modified. A numerical differentiation formula that determines estimates satisfying (7) is given. In this note, a different method is given for the numerical evaluation of (4) that satisfies (7).

The method is based only on the random variables (5) and it employs together with (6) the backward differences

$$
B^i X_{m, \delta} = \left( X_{m+1, \delta} - X_{m, \delta} \right) / \delta
$$

$$
B^i U_{m, \delta} = \left( U_{m+1, \delta} - U_{m, \delta} \right) / \delta.
$$

(8)

While the method in [2] estimated the difference from the case of continuous observations, the method presented here exploits the infinitesimal properties of the covariance function of the process. The method is more general in the sense that it applies to the case when the differentiation is subject to white noise. This generalization has the following motivation.

It is known (see, e.g., [3]) that a stationary Gaussian process $(X(t), t \in \mathbb{R})$ with the spectral density

$$
f(\lambda) = \frac{h}{|i\lambda|^d - \alpha^q (i\lambda)^{d-1} - \cdots - \alpha^{d-1}}
$$

can be represented as a solution of the stochastic differential equation

$$
dX^{(d-1)} = \left( \alpha^1 X^{(0)} + \alpha^2 X^{(1)} + \cdots + \alpha^d X^{(d-1)} \right) dt + \sqrt{h} dW
$$

(9)

where $(W(t), t \geq 0)$ is a standard Wiener process. Equation (9) is a particular case of (1). More generally, a Gaussian process with a rational spectral density

$$
f(\lambda) = \frac{|b^d |i\lambda|^d - \cdots - \alpha^{d-1}}{|i\lambda|^d - \alpha^q (i\lambda)^{d-1} - \cdots - \alpha^{d-1}}
$$

satisfies (9) where $X^{(i)}(t), i = 0, \cdots, d - 1$, denote the random processes satisfying

$$
dX^{(i)} = X^{(i)} dt + \beta_i dW, \quad i = 1, \cdots, d - 1
$$

with

$$
\beta_1 = b^d, \quad \beta_i = b^{d+1-i} + \sum_{j=1}^i \beta_j b^{d+1-j+i}.
$$

Thus, it is important to consider the following generalization of (1), (2)

$$
dX^{(i-1)}(t) = X^{(i)}(t) dt + dW^{(i)}(t), \quad i = 1, \cdots, d - 1
$$

(10)

where $(W^{(i)}(t), i = 0, \cdots, d - 1)$ is a $d \times n$-dimensional Wiener process with local variance matrix $H_0$.

II. PARAMETER ESTIMATION

Assume that (1) and (10) are satisfied with $\alpha = \alpha_0$, and let the $q$-dimensional process $(U(t), t \geq 0)$ be the solution of the linear stochastic differential equation

$$
dU(t) = c U(t) dt + dW_0(t), \quad U(0) = U_0
$$

where $c$ is a constant matrix, and $(W_0(t), t \geq 0)$ is a $q$-dimensional Wiener process with local variance matrix $h_0$ that is independent of $(W(t), W^{(1)}(t), \cdots, W^{(d-1)}(t), t \geq 0)$.

To describe the evolution of the entire model, introduce the state vector $X(t) \in \mathbb{R}^{n+q}$ and the matrices $F$, $H$ that are described in block form according to the partition of $X$

$$
X(t) = \begin{pmatrix}
X^{(0)}(t) \\
X^{(d-1)}(t) \\
U(t)
\end{pmatrix}
$$

$$
F = \begin{pmatrix}
0 & 1 & 0 & \cdots & 0 \\
0 & 0 & 1 & \cdots & 0 \\
\cdots & \cdots & \cdots & \cdots & \cdots \\
f_1 & f_2 & f_3 & \cdots & f_d \\
0 & 0 & 0 & \cdots & 0 & c
\end{pmatrix}
$$

$$
H = \begin{pmatrix}
H_0 \\
0 \\
h_0
\end{pmatrix}
$$

(11)

where $I$ denotes the identity matrix in $\mathbb{R}^n$, and

$$
f_i = f_i(\alpha_0), \quad i = 1, \cdots, d, \quad g = g(\alpha_0).\]
It easily follows that 
\[ d\mathbf{x}(t) = F\mathbf{x}(t) dt + dW(t), \quad \mathbf{x}(0) = X_0 \]
where \( (W(t), t \geq 0) \) is a \( d \cdot n + q \)-dimensional Wiener process with local variance matrix \( H \).

The following assumption is made.

**Assumption 1:** \( F \) is a stable matrix.

This assumption implies that \( \mathbf{x}(t) \) has a limiting Gaussian distribution as \( t \to \infty \) with zero mean and variance matrix \( \mathbf{R} \), which is the solution of the Lyapunov equation
\[ FR + RF^T + H = 0. \] (12)

The partition of \( \mathbf{R} \) into the blocks \( r_{ij} \) as
\[ \mathbf{R} = (r_{ij}) \] (13)
as introduced in (11) is used.

The matrix on the left-hand side of the system of equations (4) that acts on \( \alpha^*(T) \) can be written as
\[ \left( \frac{1}{T} \int_0^T \mathcal{X} F_j LF_j \mathcal{X} dt \right) \]
for \( j, k = 1, \ldots, p \) where
\[ F_j = (f_{1j}, \ldots, f_{nj}, g_j), \quad j = 1, \ldots, p. \]

By Assumption 1, this family of matrices indexed by \( T > 0 \) converges (in quadratic mean) as \( T \to \infty \) to the matrix
\[ Q = (\text{tr}(F_j LF_j \mathbf{R})) \] (14)
for \( j, k = 1, \ldots, p \) where \( \text{tr}(\cdot) \) denotes the trace operator.

Assumption 1 and the assumption of nonsingularity of \( Q \) guarantee the consistency of the family \( \{\alpha^*(T), T > 0\} \) as \( T \to \infty \), that is,
\[ \lim_{T \to \infty} \alpha^*(T) = \alpha_0 \quad \text{a.s.} \]

The discrete approximation of (4) presented here leads in the limit to a different system of equations. The associated matrix has a form similar to (14) with the matrix \( \mathbf{R} \) in (12) replaced by a matrix \( S \) which is defined subsequently. While the methods introduced in [2] estimated the difference from the case of the continuous observations, the method presented here exploits the infinitesimal properties of the covariance function.

For \( \delta > 0 \) define
\[ R(\delta) = \lim_{T \to \infty} EX(t + \delta)X(t)' \] (15)
and thus
\[ R(-\delta) = R(\delta)'. \]

**Lemma 1:** Let Assumption 1 be satisfied. For \( \delta > 0 \) the following equality is satisfied:
\[ R(\delta) = \sum_{k=0}^{\infty} \frac{\delta^k}{k!} R_k \] (16)
where
\[ R_k = r_{k+1,1}, \quad k = 0, 1, \ldots, d - 1 \]
\[ R_k = f_1 R_{k-d} + f_2 R_{k+1-d} + \cdots + f_d R_{d-k-d} + (-1)^k g r_{d+1, k+1-d}, \quad k = d, d + 1, \ldots, 2d - 1. \] (17)

**Proof:** From the theory of linear stochastic systems, it follows that for \( \delta > 0 \)
\[ R(\delta) = \left( \sum_{k=0}^{\infty} \frac{\delta^k}{k!} R_k \right)_{11} \] (19)
where \( (A)_{ij} \) denotes the block \( a_{ij} \) of the matrix \( A \) using the partitioning in (11). Consequently,
\[ R_k = (F^k \mathbf{R})_{11}, \quad k = 0, 1, \ldots. \] (20)

Obviously, \( R_0 = r_{11} \), and performing successive multiplications on \( \mathbf{R} \) by \( F \), it follows that
\[ R_1 = r_{21}, \ldots, R_{d-1} = r_{d1}. \]

Furthermore, using (18), it follows that
\[ (F^{d+1} \mathbf{R})_{d1} = (F^{d-1} F^{d+1} \mathbf{R})_{11} = R_{d+1}. \] (21)

Hence,
\[ FR = \begin{pmatrix} R_1 & \cdots \\ \vdots & \ddots \\ R_d & \cdots & cr_{d+1,1} & \cdots & cr_{d+1,d+1} \end{pmatrix} \]
This equality yields (18) for \( k = 0 \).

By the Lyapunov equation (12)
\[ cr_{d+1,j} = -r_j \quad d+1 = -r_{d+1,j+1}, \quad j = 1, \ldots, d + 1. \]

Consequently,
\[ cr_{d+1,1} = (-1)^d r_{d+1,k+1}, \quad k = 1, \ldots, d - 1. \] (22)

Using (21) and (22), it follows that
\[ R_{d+h} = (F^{h} \mathbf{R})_{d1} = \begin{pmatrix} R_k & \cdots \\ \vdots & \ddots \\ g r_{d+1,1} & \cdots & \end{pmatrix}_{d1} = f_1 R_k + \cdots + f_d R_{d-k-1} + g r_{d+1,1}. \]

This equality and (22) yield (18) for \( k = 1, \ldots, d - 1. \)

Consider next the observed random variables (5), and note that it follows from (6) and (8), respectively, that
\[ D^r X_{m,r} = \frac{1}{\delta^r} \sum_{k=0}^{\infty} (-1)^k \delta^k X_{m+r-k, \delta} \] (23)
\[ B^s X_{m,s} = \frac{1}{\delta^s} \sum_{k=0}^{\infty} (-1)^k \delta^k X_{m-s+k, \delta}. \] (24)

**Lemma 2:** Let Assumption 1 be satisfied. For \( r, s = 0, 1, \ldots, \) the following equality is satisfied:
\[ \lim_{\delta \to 0} \lim_{N \to \infty} \frac{1}{N} \sum_{m=s}^{N-s} D^r X_{m,s} B^s X_{m,s} = R_{r+s}. \] (25)
From this equality, (22) follows.

From (20), (23), and (24), it follows that

\[ r_{j+1,i} = (\mathbf{FR})_{j,i}, \quad i = 1, \ldots, d - 1; \quad j = d + 1, \ldots, d + q \]

so that,

\[ (-1)^v r_{j,i+v+1, d+1+v} = r_{j+1,i+v} = r_{j+1,i+v} \]

which yields (26).

Similarly, to verify (27), it follows as in (30) that

\[ \lim_{\delta \to 0} \lim_{N \to \infty} \frac{1}{N} \sum_{m=0}^{N-1} D^x X_{m, \delta} \mathbf{T}_m, \delta = (-1)^v (\mathbf{FR})_{d, d+1+v} \]

For \( v = 0 \), the last term in the equality coincides with the right-hand side of (26). For \( v > 0 \), it follows from (12) that

\[ \lim_{\delta \to 0} \lim_{N \to \infty} \frac{1}{N} \sum_{m=0}^{N-1} D^x X_{m, \delta} \mathbf{T}_m, \delta = (-1)^v (\mathbf{FR})_{d, d+1+v} \]

Repeating this argument, it follows that

\[ (-1)^v (\mathbf{FR})_{d, d+1+v} = (\mathbf{FR})_{d, d+1} \]

which establishes (27).

Now the discrete observation version of (4) is introduced by letting the estimate \( \hat{\alpha}_{N, \delta} \) be the solution of

\begin{align*}
\sum_{k=1}^{p} \frac{1}{N} \sum_{m=0}^{N-1} \left( \sum_{l=1}^{d} f_{ij} B^{j-l} U_{m, \delta} + g_{ij} U_{m, \delta} \right) \\
\times L \left( \sum_{h=1}^{d} f_{h,k} D^{h-1} X_{m, \delta} + g_{h,k} U_{m, \delta} \right) \hat{\alpha}_{N, \delta}^k \\
= \frac{1}{N} \sum_{m=0}^{N-1} \sum_{l=1}^{d} f_{lij} D^{j-l} X_{m, \delta} + g_{lij} U_{m, \delta} \\
\times L \left( D^{j-l} X_{m, \delta} - \sum_{h=1}^{d} f_{h,0} D^{h-1} X_{m, \delta} - g_{0} U_{m, \delta} \right)
\end{align*}

for \( j = 1, \ldots, d \). To guarantee the consistency of \( \hat{\alpha}_{N, \delta} \) as \( N \to \infty \) and \( \delta \to 0 \), a matrix \( \mathbf{Q} \) that is analogous to \( \mathbf{Q} \) in (14) is introduced by replacing \( \mathbf{R} \) by a matrix \( \mathbf{S} \). Let \( \mathbf{R}_0, \ldots, \mathbf{R}_{d-1}, \mathbf{R}_d, \ldots, \mathbf{R}_{d-1}, d \) be given by (13), (17), and (18). Define

\[ \mathbf{S} := \begin{pmatrix} \mathbf{R}_0 & \mathbf{R}_1 & \cdots & \mathbf{R}_{d-1} & \mathbf{R}_d \\
\mathbf{R}_1 & \mathbf{R}_2 & \cdots & \mathbf{R}_{d} & \cdots \\
\vdots & \ddots & \cdots & \cdots & \cdots \\
\mathbf{R}_{d-1} & \cdots & \cdots & \cdots & \mathbf{R}_{d-1, d} \\
\mathbf{R}_{d, d} & \cdots & \cdots & \cdots & \mathbf{R}_{d+1, d} \end{pmatrix} \quad (32) \]

The matrix \( \mathbf{Q} \) is given in the following theorem.

**Theorem 2:** The matrix

\[ \hat{\mathbf{Q}} := \left( \text{tr} (F_{j,k}^2 L \mathbf{Q} \mathbf{S}) \right), \quad j, k = 1, \ldots, p \]

is nonsingular.

**Theorem 1:** Let Assumptions 1 and 2 be satisfied, and let \( \hat{\alpha}_{N, \delta} \) be the solution of (31). Let \( (X(t), t \geq 0) \) be \( r \)-times differentiable and \( \mathbf{U}(t), t \geq 0 \) be \( s \)-times differentiable (in quadratic mean), and let \( r + s \geq d - 1 \). Then

\[ \lim_{\delta \to 0} \lim_{N \to \infty} \hat{\alpha}_{N, \delta} = \alpha_0. \]
Fig. 1 Convergence of the estimator.

Proof: It is sufficient to prove that the system of equations, which is obtained by performing the two passages to the limit, that is, \( N \to \infty \) and \( \delta \to 0 \) in (31), has the unique solution \( \alpha_0 \).

If \( N \to \infty \) and \( \delta \to 0 \) in (31), then the following family of linear equations for the estimate \( \hat{\alpha}_{\infty,0} \) is obtained by Lemmas 2 and 3.

\[
\sum_{k=1}^{p} \left\{ \text{tr} \left( L \left[ \sum_{l=1}^{p} f_{l,k} R_{l,k-1} f_{l,j} + \sum_{l=1}^{p} g_{l,k} \pi_l f_{l,j} + \sum_{l=1}^{p} g_{l,k} \pi_l^2 f_{l,j} + \sum_{l=1}^{p} f_{l,k} \pi_l g_{l,j} + g_{l,k} \pi_l^2 g_{l,j} \right] \right) \right\} = 0
\]

By Lemma 1, the first two sums in the square bracket equals
\[
\sum_{j=1}^{p} R_{j,k-1} f_{j,j}
\]

Consequently, (37) is equal to the right-hand side of (35). \( \square \)

The quadratic mean differentiability of a process is determined by the differentiability of its covariance function

**Example:** Let \((X(t), t \in \mathbb{R})\) be a stationary Gaussian process with the covariance function

\[
R(\delta) = R_0 e^{-a|\delta|} \cos b\delta
\]

where \( a, b \) are positive, unknown constants. The spectral density corresponding to (38) is

\[
f(\lambda) = 2R_0a \left| \frac{1}{(i\lambda)^2 + 2a\lambda + a^2 + b^2} \right|^2
\]

Furthermore, it follows from (38) or (39) that

\[
dX = X^{(1)} dt + \beta_1 dW
\]

\[
dX^{(1)} = \alpha_0^1 X dt + \alpha_0^2 X^{(1)} dt + \beta_2 dW
\]

where

\[
\alpha_0^1 = -a^2 + b^2, \quad \alpha_0^2 = -2a
\]

\[
\beta_1 = \sqrt{2R_0a}, \quad \beta_2 = \sqrt{2R_0a(\sqrt{a^2 + b^2} - 2a)}
\]

The parameter \( \alpha_0 = (\alpha_0^1, \alpha_0^2) \) is estimated by (4) and (35) and \( \beta_1 \) is estimated by the quadratic variation of \((X(t), t \geq 0)\). Estimates of \( a, b \) and \( R_0 \) are obtained from (40) and (41). Expanding \( R(\delta) \) in terms of \( \delta \) it follows that

\[
R(\delta) = R_0(1 - a|\delta| + \frac{1}{2}(a^2 - b^2)|\delta|^2 + \frac{1}{4}(3a^2 - a^3)|\delta|^3 + \cdots)
\]

Letting \( L = I \) in (3), it is expressed as

\[
\int_0^T \left[ \left( X^{(2)} - \alpha_1^1 X - \alpha_0^2 X^{(1)} \right)^2 - \left( X^{(2)} \right)^2 \right] dt
\]
so (4) is

\[
\frac{1}{T} \int_0^T (X^2) dt \alpha^{-1}(T) + \frac{1}{T} \int_0^T XX(1) dt \alpha^{-2}(T) = \frac{1}{T} \int_0^T XX(1) dX(1)^T
\]

(42)

\[
\frac{1}{T} \int_0^T XX(1) dt \alpha^{-1}(T) + \frac{1}{T} \int_0^T (X(1)^T)^2 dt \alpha^{-2}(T) = \frac{1}{T} \int_0^T X(1)^T dX(1).
\]

(43)

In the limit as \( T \to \infty \), there are the two equations

\[
R_0 \alpha^{-1}(\infty) - a R_0 \alpha^{-2}(\infty) = R_0\alpha^0_1 - a R_0 \alpha^0_2
\]

(44)

\[
ar R_0 \alpha^{-1}(\infty) + r_22 \alpha^{-2}(\infty) = \alpha^0_1 a R_0 + \alpha^0_2 r_22.
\]

(45)

For the discretized version (31) of (42), (43), the limit as \( N \to \infty \) and \( \delta \to 0 \) is different from (44), (45), specifically

\[
R_0 \hat{\alpha}^{-1}(\infty) - a R_0 \hat{\alpha}^{-2}(\infty) = R_0(a^2 - b^2)
\]

(46)

\[
- a R_0 \hat{\alpha}^{-1}(\infty) + R_0(a^2 - b^2) \hat{\alpha}^{-2}(\infty) = R_0(3a b^2 - a^3).
\]

(47)

The solution is \( \hat{\alpha}^{-1} = \alpha_0 \).

The quadratic variation can be used to estimate \( \beta^2_1 \) by

\[
\hat{\beta}^2_1 = \frac{1}{N \delta} \sum_m (X_{m+1, \delta} - X_m)^2.
\]

A numerical example is described graphically (see Fig. 1) where \( a = 0.5, b = 2.0 \), and \( R_0 = 1 \) so that \( \alpha_1 = -4.25 \) and \( \alpha_2 = -1.0 \). The convergence of family of estimates is relatively fast. If a longer time interval is used, then the family of estimates for \( \alpha_1 \) are closer to the true value.

The authors thank Y. Yan for performing the computations for the numerical example. The authors also thank the referees for useful comments that improved the note.

**REFERENCES**

**Stochastic Control of Discrete Systems: A Separation Principle for Wiener and Polynomial Systems**

M. J. Grimble

*Abstract—* A new separation principle is established for systems represented in discrete frequency-domain Wiener or polynomial forms. The LQG or \( H_2 \) optimal controller can be realized using an observer based structure estimating noise free output variables that are fed back through a dynamic gain control block. Surprisingly, there are also two separation principle theorems, depending upon the order in which the ideal output optimal control and the optimal observer problems are solved.

*Index Terms—* Optimal control, polynomial systems, Wiener theory.

**I. INTRODUCTION**

The separation principle of stochastic optimal control theory has often been utilized for systems represented in state equation form. However, no such results have been established for systems represented in transfer-function or polynomial matrix form. The frequency domain approach to optimal control and estimation was initiated by Wiener [1], but two seminal contributions later established the main tools for synthesis. These contributions were undertaken in the same period by Youla et al. [2] and by Kucera [3].

The separation principle that is well known in state-space LQG synthesis was not used in the frequency-domain solutions, although Kucera [4] provided independent solutions of the LQ state feedback control and the Kalman filtering problems. Thus, in this case, if the polynomial models are related back to a system described in state equation form, it is possible to use the polynomial solutions to calculate the constant control and filter gains. The state-space separation principle results can then be invoked to obtain the LQG output feedback controller. The separation principle was not, however, established in the polynomial setting. Moreover, there was no attempt to generalize the results to the case where the control law feedback included a reduced set of variables, such as plant output estimates. The objective of the analysis that follows is to use frequency domain models and analysis, to establish a new separation principle result for systems represented in frequency domain matrix fraction form.

**II. POLYNOMIAL SYSTEM DESCRIPTION**

The linear time-invariant discrete-time multivariable, finite-dimensional system of interest is illustrated in Fig. 1. The noise free system output sequence is denoted by \( \{ y(t) \} \), where \( y(t) \in R^r \), and the observations signal is denoted by \( \{ z(t) \} \). The white driving noise \( \{ \xi(t) \} \) and \( \{ v(t) \} \) represent the disturbance, and measurement noise signals, respectively. These signals are statistically independent and the covariance matrices \( (R_f > 0)\):

\[
\text{cov}[\xi(t), \xi(\tau)] = I_\delta \beta_{1r} \quad \text{and} \quad \text{cov}[v(t), v(\tau)] = R_f \delta_{tr}.
\]
