(CLEO Collaboration)  
 (Received 19 October 1995)

This paper describes new measurements from CLEO of the inclusive  $B \rightarrow D_s^+ X$  branching fraction as well as the  $B^+ \rightarrow D_s^{(*)+} \bar{D}^{(*)0}$  and  $B^0 \rightarrow D_s^{(*)+} D^{(*)-}$  branching fractions. The inclusive branching fraction is  $\mathcal{B}(B \rightarrow D_s^+ X) = (12.11 \pm 0.39 \pm 0.88 \pm 1.38)\%$  where the first error is statistical, the second is the systematic error, and the third is the error due to the uncertainty in the  $D_s^+ \rightarrow \phi \pi^+$  branching fraction. The branching fractions for the  $B \rightarrow D_s^{(*)+} \bar{D}^{(*)}$  modes are found to be between 0.9% and 2.4% and are significantly more precise than previous measurements. The sum of the  $B \rightarrow D_s^{(*)+} \bar{D}^{(*)}$  branching fractions is consistent with the results of fits to the inclusive  $D_s^+$  momentum spectrum. Factorization is used to arrive at a value for  $f_{D_s}$ , the  $D_s^+$  decay constant.

PACS number(s): 13.25.Hw

## I. INTRODUCTION

The large samples of  $B$  mesons being collected by experimental groups at  $e^+e^-$  and hadron colliders have allowed for ever more precise measurements of  $B$  meson decay properties. Theoretical calculations are unable to simultaneously describe the total inclusive  $B$  to charm rate and the semileptonic branching fraction of the  $B$  meson [1]. It has been conjectured that  $b$  quark to charm quark transitions where the  $W^+$  materializes as  $\bar{c}s$  are large [2]. The external spectator  $B$  meson decay diagram, shown in Fig. 1, leads to a  $D_s^{(*)+}$  in the final state whereas the internal  $W^+$  decay diagram results in the production of charmonium [3]. This paper reports new measurements of  $B \rightarrow D_s^+ X$  decays from CLEO.<sup>1</sup>

After a short description of the detector and the criteria used to select neutral and charged particle candidates, there are two sections dealing with the measurements of the inclu-

sive  $B \rightarrow D_s^+ X$  branching fraction and the exclusive  $B \rightarrow D_s^{(*)+} \bar{D}^{(*)}$  branching fractions. Under the assumption that the charged and neutral  $B$  decay rates and lifetimes are equal, the charged and neutral  $B$  branching fractions are averaged and compared with theoretical predictions. This is followed by a discussion of a fit to the inclusive  $D_s^+$  momentum spectrum. The final section describes two methods using factorization to extract  $f_{D_s}$ , the  $D_s^+$  decay constant.

## II. EVENT AND TRACK SELECTION

The data used in this analysis were selected from hadronic events produced in  $e^+e^-$  annihilations at the Cornell Electron Storage Ring (CESR). The data sample consists of an integrated luminosity of  $2.03 \pm 0.04 \text{ fb}^{-1}$  collected at the  $Y(4S)$  resonance (referred to as on-resonance data) and  $0.97 \pm 0.02 \text{ fb}^{-1}$  at a center-of-mass energy just below the

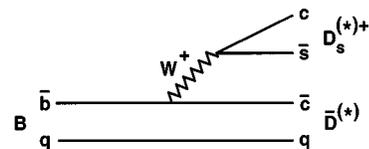

FIG. 1. The spectator diagram for  $B \rightarrow D_s^{(*)+} \bar{D}^{(*)}$  decay.

\*Permanent address: University of Hawaii at Manoa.

<sup>1</sup>Reference to a specific state or decay means that the charge-conjugate state or decay has been included. The notation  $D_s^{+(*)}$  in this context means either  $D_s^+$  or  $D_s^{*+}$ . In  $B \rightarrow D_s^{(*)+} \bar{D}^{(*)}$ ,  $\bar{D}$  is a generic representation of the  $\bar{c}q$  mesons, the  $D^-$  and  $\bar{D}^0$ , while the symbol  $(*)$  implies that the branching fraction for both the nonexcited and excited states of the meson were separately measured.

threshold for producing  $B\bar{B}$  mesons (referred to as off-resonance or continuum data). The on-resonance data corresponds to  $(2.19 \pm 0.04) \times 10^6 B\bar{B}$  pairs.

The CLEO II detector measures both neutral and charged particles with excellent resolution and efficiency [4]. Hadronic events are selected by requiring a minimum of three charged tracks, a total visible energy greater than 15% of the center-of-mass energy (this reduces contamination from two-photon interactions and beam-gas events), and a primary vertex within  $\pm 5$  cm in the  $z$  direction and  $\pm 2$  cm in the  $r$ - $\phi$  plane of the nominal collision point. Since the  $B$  mesons are produced almost at rest, their decay products are uniformly distributed throughout the volume of the detector leading to events that tend to be ‘spherical’ in shape. Continuum  $e^+e^- \rightarrow q\bar{q}$  ( $q=u,d,s,c$ ) events are more jetlike in structure. The shape variable  $R_2$ , which is the ratio of the second Fox-Wolfram moment to the zeroth moment [5], is found to be useful in discriminating between  $B\bar{B}$  events and those in which lighter mass quarks are produced. Only events with  $R_2 < 0.35$  are used in this analysis.

All charged tracks are required to be consistent with having originated from within  $\pm 5$  cm in the  $z$  direction and  $\pm 5$  mm in the  $r$ - $\phi$  plane of the primary vertex. Tracks are also required to have  $dE/dx$  information which is consistent with the proposed particle hypothesis.

### III. THE INCLUSIVE $B \rightarrow D_s^+ X$ BRANCHING FRACTION

The  $D_s^+$  mesons in the on-resonance data set originate from  $B$  meson decays and from continuum production via  $e^+e^- \rightarrow c\bar{c}$ . Therefore, in order to measure  $\mathcal{B}(B \rightarrow D_s^+ X)$ , it is necessary to subtract the continuum contribution from the total yield of  $D_s^+$  mesons in the on-resonance data set.

The  $D_s^+ \rightarrow \phi\pi^+, \phi \rightarrow K^+K^-$  decay channel was chosen for the inclusive  $B \rightarrow D_s^+ X$  measurement because it offers the best combination of detection efficiency, branching fraction, and signal to background ratio. The  $K^+K^-$  invariant mass is required to be within 10 MeV of the  $\phi$  mass. Two angles are useful for suppressing background: (1) the  $\phi$  helicity angle  $\theta_H$ , which is the angle in the  $\phi$  rest frame between the direction of the  $K^+$  and the  $D_s^+$  direction, and (2) the  $D_s^+$  decay angle  $\theta_D$ , which is the angle in the  $D_s^+$  rest frame between the  $\phi$  direction and  $D_s^+$  direction in the lab frame. The signal follows a  $\cos^2\theta_H$  distribution while the background is flat in  $\cos\theta_H$  so requiring  $|\cos\theta_H| > 0.35$  eliminates 35% of the background events while retaining 96% of the signal. The  $\cos\theta_D$  distribution for the signal is flat. The  $\cos\theta_D < 0.75$  requirement suppresses combinatorial background from abundant low momentum pions that peaks near  $\cos\theta_D = 1$ .

The efficiency of these selection criteria is calculated from a Monte Carlo simulation. Figure 2 shows the  $D_s^+$  detection efficiency as a function of  $x$ , the scaled  $D_s^+$  momentum, where  $x \equiv p_{D_s^+}/p_{\max}$  and  $p_{\max} = \sqrt{E_{\text{beam}}^2 - m_{D_s^+}^2}$ . The end point for  $D_s^+$  mesons produced in  $B$  decay is  $x = 0.46$ .

The on-resonance yield of  $D_s^+$  mesons as a function of scaled momentum is extracted by fitting the  $\phi\pi^+$ -invariant mass plot in bins of  $x$ . The bin size of 0.03 is an order of magnitude larger than the resolution in  $x$ . The fitting func-

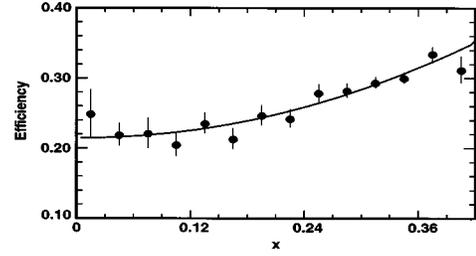

FIG. 2. The efficiency for reconstructing  $D_s^+ \rightarrow \phi\pi^+$ ,  $\phi \rightarrow K^+K^-$  as a function of scaled  $D_s^+$  momentum for the selection criteria described in the text. The curve is the result of fitting a 2nd order polynomial to the data points.

tion consists of a straight line parametrization of the combinatorial background and a Gaussian describing the signal. The width of the Gaussian is fixed to the value found from fitting the Monte Carlo sample. The rms resolution increases linearly with momentum from 6 MeV at low momentum to 8 MeV as  $x$  approaches 1. The  $D_s^+$  mass was allowed to vary as a function of momentum in a first pass of fitting to the data and then was fixed to the average value of 1.9686 GeV in the final pass. For illustration purposes, the  $\phi\pi^+$  mass spectra and resultant fits for an  $x$  bin width of 0.07 are shown in Fig. 3. The  $D_s^+$  momentum spectrum before efficiency correction is shown in Fig. 4.

The fact that there are no  $D_s^+$  mesons from  $B$  decay with  $x > 0.5$  is used to create a continuum momentum spectrum with maximum statistics. The momentum spectrum for continuum-produced  $D_s^+$  mesons is constructed from the sum of the on- and off-resonance data for  $x > 0.5$  and only the off-resonance data, scaled by the ratio of on/off luminosities, for  $x < 0.5$ . The number of  $D_s^+$  mesons per momentum bin for this ‘constructed’ continuum data sample is ex-

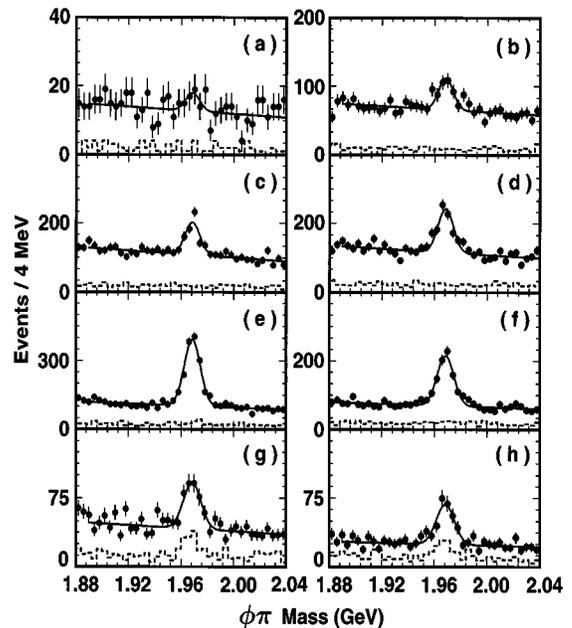

FIG. 3. The  $\phi\pi^+$  mass spectra for the on-resonance (points with error bars) and unscaled off-resonance (hatched histogram) data sets in  $x$  bins of 0.07 from (a)  $0.0 \leq x < 0.07$  to (h)  $0.49 \leq x < 0.56$ .

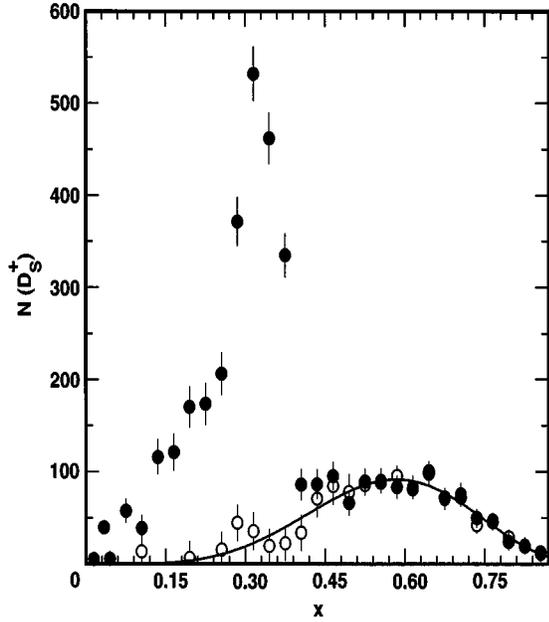

FIG. 4. The on-resonance (solid dots) and scaled ‘‘constructed’’ continuum (open circles)  $D_s^+$  momentum spectra before efficiency correction. The function is the result of the fit described in the text.

tracted in the same manner as described above. The resulting continuum  $D_s^+$  momentum spectrum, properly rescaled, is shown in Fig. 4. It is fit with a function that was found to describe the Monte Carlo continuum  $D_s^+$  momentum spectrum. The values of this function, also shown in Fig. 4, are subtracted, bin by bin, from the on-resonance  $D_s^+$  momentum spectrum to give the raw (i.e., not efficiency corrected) yield of  $2537 \pm 83$   $D_s^+$  mesons produced in  $B$  decays.

Figure 5 shows the  $D_s^+$  momentum spectrum after con-

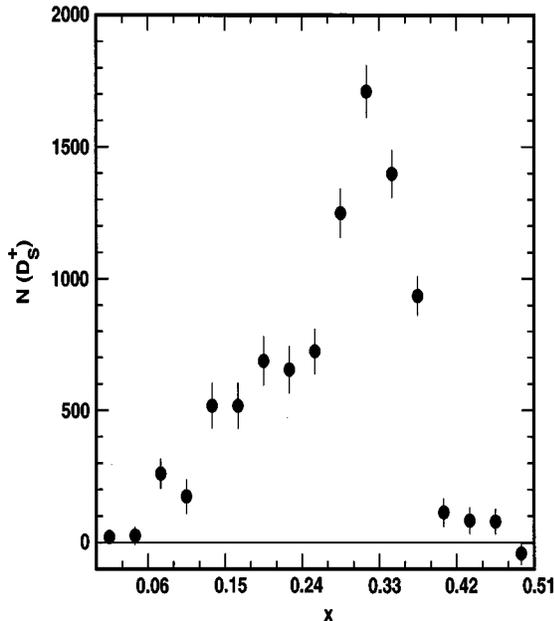

FIG. 5. The continuum-subtracted, efficiency-corrected yield of  $D_s^+$  mesons as a function of  $x$ .

TABLE I. Measurements of  $\mathcal{B}(B \rightarrow D_s^+ X)$ . The first error is statistical and the second is the systematic error. A value of  $\mathcal{B}(D_s^+ \rightarrow \phi \pi^+) = (3.5 \pm 0.4)\%$  is common to all measurements so the error on this quantity is not included in the systematic errors.

Experiment	$\mathcal{B}(B \rightarrow D_s^+ X)$
CLEO II	$(12.11 \pm 0.39 \pm 0.88) \%$
ARGUS(92) [7]	$(8.34 \pm 1.11 \pm 0.89) \%$
CLEO-1.5 [8]	$(8.74 \pm 1.31 \pm 0.86) \%$
ARGUS(87) [9]	$(12.1 \pm 3.4) \%$
CLEO-I [10]	$(10.9 \pm 2.9) \%$

tinuum subtraction and correction for detection efficiency. From the total yield of  $9111 \pm 299$   $D_s^+$  mesons from  $B$  decay, the inclusive branching fraction is calculated to be

$$\mathcal{B}(B \rightarrow D_s^+ X) = \left[ (12.11 \pm 0.39 \pm 0.88) \times \left( \frac{3.5 \pm 0.4\%}{\mathcal{B}(D_s^+ \rightarrow \phi \pi^+)} \right) \right] \%,$$

where the first error is statistical, the second is the systematic error, and the third error is due to the uncertainty in the  $D_s^+ \rightarrow \phi \pi^+$  branching fraction [6]. This value for  $\mathcal{B}(B \rightarrow D_s^+ X)$  is larger than the previous CLEO and ARGUS measurements shown in Table I.

The largest error in the measurement is the 11% uncertainty in the  $D_s^+ \rightarrow \phi \pi^+$  branching fraction. This error is displayed separately to distinguish it from the 7.2% systematic error associated with detector effects and the analysis method. The contributions to the systematic error are listed in Table II. The uncertainties in the number of  $B\bar{B}$  pairs and in the  $\phi \rightarrow K^+ K^-$  branching fraction are included but the dominant source is the uncertainty in the tracking efficiency. A 2% per track uncertainty in the track finding efficiency

TABLE II. Systematic errors for  $\mathcal{B}(B \rightarrow D_s^+ X)$ .

Source	Error(%)
Signal shape	1.46
Background shape	0.36
Continuum subtraction	0.30
$x$ dependence of the efficiency	1.97
Bin width	0.99
$\phi$ mass interval	0.52
Particle identification criteria	0.67
$R_2$	0.72
Track quality criteria	0.27
Angular selection criteria	1.12
Monte Carlo statistics	0.29
Total for $D_s^+$ yield	3.14
$\mathcal{B}(\phi \rightarrow K^+ K^-)$	1.83
Number of $B\bar{B}$	1.80
Tracking efficiency	6.00
Total systematic error	7.24

TABLE III. The  $D_s^{(*)+}$  mass intervals and branching fractions.

Decay mode	Mass or $\Delta M$ interval (GeV)	Branching fraction
$D_s^{*+} \rightarrow D_s^+ \gamma$	$0.132 < m_{D_s^{*+}} - m_{D_s^+} < 0.152$	1.0
$D_s^+ \rightarrow \phi \pi^+$	$1.9542 < m_{\phi \pi^+} < 1.9822$	$0.035 \pm 0.004$
Decay mode	Mass interval (GeV)	$\mathcal{B}/\mathcal{B}(D_s^+ \rightarrow \phi \pi^+)$
$D_s^+ \rightarrow K^0 K^+$	$1.9532 < m_{K_S^0 K^+} < 1.9832$	$1.01 \pm 0.25$
$D_s^+ \rightarrow K^{*0} K^+$	$1.9530 < m_{K^{*0} K^+} < 1.9835$	$0.95 \pm 0.10$
$D_s^+ \rightarrow \phi \rho^+$	$1.9442 < m_{\phi \rho^+} < 1.9922$	$1.86 \pm 0.48$
$D_s^+ \rightarrow \eta \pi^+$	$1.9374 < m_{\eta \pi^+} < 1.9990$	$0.54 \pm 0.11$
$D_s^+ \rightarrow \eta \rho^+$	$1.9338 < m_{\eta \rho^+} < 2.0036$	$2.86 \pm 0.54$

results in a 6% systematic error for the  $D_s^+ \rightarrow \phi \pi^+$ ,  $\phi \rightarrow K^+ K^-$  decay chain. The other sources of systematic error on the  $D_s^+$  yield listed in Table II contribute 3.1% to the total systematic error.

#### IV. EXCLUSIVE $B \rightarrow D_s^{(*)+} \bar{D}^{(*)0}$ DECAYS

The near hermeticity of the CLEO II detector coupled with its excellent photon detection and charged particle reconstruction capabilities allow for the reconstruction of all eight  $B^0 \rightarrow D_s^{(*)+} D^{(*)-}$  and  $B^+ \rightarrow D_s^{(*)+} \bar{D}^{(*)0}$  modes. The  $D_s^{(*)+}$  and  $D^{(*)}$  decay channels used, the mass selection criteria, and the assumed branching fractions, are given in Tables III and IV. The allowed mass intervals correspond to 2.5 standard deviations for channels where the mass resolution dominates the observed width, and to one natural width otherwise. The  $D_s^+$  and  $D^0$  branching fractions are given relative to those for the two normalizing modes:  $D_s^+ \rightarrow \phi \pi^+$  and  $D^0 \rightarrow K^- \pi^+$ . The values for all absolute branching fractions and relative branching ratios are taken from [6] except for  $\mathcal{B}(D^0 \rightarrow K^- \pi^+)$  [11],  $\mathcal{B}(D^+ \rightarrow K^- \pi^+ \pi^+)/\mathcal{B}(D^0 \rightarrow K^- \pi^+)$  [12], and the  $D^*$  branching fractions [13], where CLEO measurements are used since they dominate the world average and their use allows for the cancellation of some common systematic errors.

The data sample and the event selection criteria are the same as were used in the inclusive analysis. The track quality criteria are also the same except for the ‘‘slow’’  $\pi^+$  from  $D^{*+} \rightarrow D^0 \pi^+$  decays which has just the  $r$ - $\phi$  distance of

closest approach requirement applied. Photon candidates are required to have deposited more than 30 MeV of energy in the calorimeter, to be isolated from charged tracks, and to have a lateral energy deposition consistent with that expected for a photon. Photons used for reconstructing the  $D_s^{*+} \rightarrow D_s^+ \gamma$  decay chain have a minimum energy requirement of 90 MeV and must have been detected within the ‘‘barrel’’ region of the detector, defined by  $|\cos\theta| < 0.707$  where  $\theta$  is the angle between the photon momentum vector and the  $z$  axis. For  $\pi^0$  or  $\eta$  mesons, one of the daughter photons can be from outside of the barrel where the minimum photon energy requirement is raised to 50 MeV.

The allowed mass intervals and branching fractions for the various noncharmed resonances used in this analysis are given in Table V. In  $\pi^0/\eta$  decays to two photons, the decay angle  $\theta_D$ , which is the angle in the  $\pi^0/\eta$  rest frame between the direction of one the photons and the  $\pi^0/\eta$  direction in the lab frame, can be used to reduce combinatorial background from low energy photons. A  $|\cos\theta_D| < 0.9$  criterion is used.

Since the  $Y(4S)$  decays only to  $B\bar{B}$ , the  $B$  meson energy is equal to the beam energy. This can be used to select  $B$  meson candidates by requiring that  $\Delta E$ , the difference between the measured sum of the charged and neutral energies of the daughters of the  $B$  candidate and the beam energy, be close to zero. The  $D_s^{(*)+}$  and  $D^{(*)}$  candidates, as well as the  $\pi^0$  and  $\eta$  candidates, are kinematically fitted to their known masses so as to improve the resolution in  $\Delta E$ . The  $\Delta E$  resolution is about 10 MeV and is independent of decay mode

TABLE IV. The  $D^{(*)}$  mass intervals and branching fractions.

Decay mode	Mass or $\Delta M$ interval (GeV)	Branching fraction
$D^{*+} \rightarrow D^0 \pi^+$	$0.1430 < m_{D^{*+}} - m_{D^0} < 0.1480$	$0.681 \pm 0.010$
$D^{*0} \rightarrow D^0 \pi^0$	$0.1406 < m_{D^{*0}} - m_{D^0} < 0.1446$	$0.636 \pm 0.023$
$D^0 \rightarrow K^- \pi^+$	$1.8457 < m_{K^- \pi^+} < 1.8833$	$0.0391 \pm 0.0008$
Decay mode	Mass interval (GeV)	$\mathcal{B}/\mathcal{B}(D^0 \rightarrow K^- \pi^+)$
$D^0 \rightarrow K^- \pi^+ \pi^0$	$1.8355 < m_{K^- \pi^+ \pi^0} < 1.8935$	$3.43 \pm 0.24$
$D^0 \rightarrow K^- \pi^+ \pi^- \pi^+$	$1.849 < m_{K^- \pi^+ \pi^- \pi^+} < 1.8800$	$2.02 \pm 0.11$
$D^+ \rightarrow K^- \pi^+ \pi^+$	$1.8530 < m_{K^- \pi^+ \pi^+} < 1.8856$	$2.35 \pm 0.16$

TABLE V. Allowed mass intervals and branching fractions for the noncharmed mesons.

Decay mode	Mass interval (GeV)	Branching fraction
$\pi^0 \rightarrow \gamma\gamma$	$0.1200 < m_{\gamma\gamma} < 0.1500$	$0.9880 \pm 0.0003$
$\eta \rightarrow \gamma\gamma$	$0.5174 < m_{\gamma\gamma} < 0.5774$	$0.388 \pm 0.005$
$K^0 \rightarrow K_S^0 \rightarrow \pi^+ \pi^-$	$0.4877 < m_{\pi^+ \pi^-} < 0.5077$	$0.3431 \pm 0.0014$
$\phi \rightarrow K^+ K^-$	$1.0095 < m_{K^+ K^-} < 1.0295$	$0.491 \pm 0.009$
$K^{*0} \rightarrow K^+ \pi^-$	$0.8461 < m_{K^+ \pi^-} < 0.9461$	0.667
$\rho^+ \rightarrow \pi^+ \pi^0$	$0.6161 < m_{\pi^+ \pi^0} < 0.9201$	1.0

according to a Monte Carlo simulation of  $B \rightarrow D_s^{(*)+} \bar{D}^{(*)}$  events.<sup>2</sup> All  $B$  candidates must have  $|\Delta E| \leq 25$  MeV. In the case of multiple candidates in a specific  $B$  meson decay chain, only the candidate with the smallest absolute value of  $\Delta E$  is selected. The  $B$  mass resolution can be improved by using the beam-constrained mass ( $M_B$ ), defined by

$$M_B^2 = E_{\text{beam}}^2 - \left( \sum_i \vec{p}_i \right)^2, \quad (1)$$

where  $\vec{p}_i$  is the momentum of the  $i$ th daughter of the  $B$  candidate. The  $M_B$  resolution of about 2.6 MeV is determined by the beam energy spread and is a factor of 10 better than the resolution in invariant mass obtained from simply summing the four-momenta of the  $B$  daughters.

Two other useful variables are the  $B$  production angle  $\theta_B$ , which is the angle between the  $B$  meson direction in the lab frame and the beam axis, and the sphericity angle  $\theta_S$ , which is the angle between the sphericity axis of the particles which form the  $B$  candidate and the sphericity axis of the other particles in the event. For  $B$  mesons, the production angle follows a  $\sin^2 \theta_B$  distribution whereas the continuum background is flat in this variable. Conversely, continuum events have large values of  $\cos \theta_S$  whereas the signal is flat in  $\cos \theta_S$ . The production and sphericity angle criteria are  $B$  decay channel dependent because of differing background levels. A helicity angle requirement is also used for the  $D_s^+ \bar{D}^*$  final states where the signal follows a  $\cos^2 \theta_H$  distribution, and for the  $D_s^{*+} \bar{D}$  final states where the signal follows a  $\sin^2 \theta_H$  distribution. The values of the angular selection criteria used in the analysis are given in Table VI.

The beam-constrained mass plot for the sum of the eight  $B^0$  and  $B^+$  decay channels is shown in Fig. 6. The function which is fitted to the data to extract the yield of  $B$  mesons contains two parts: (1) a background function which is linear for  $M_B < 5.282$  GeV and parabolic, with a kinematic cutoff, for larger values of  $M_B$  [14], and (2) a Gaussian to describe the signal. The background function is forced to simultaneously fit the beam-constrained mass distribution for the  $\Delta E$  sideband, defined by  $30 < |\Delta E| < 55$  MeV, so as to better constrain the shape of the background. This is essential for some of the decay channels where the number of background events is insufficient to constrain the background. The mass

<sup>2</sup>This occurs because the low momentum  $\pi^+$ ,  $\pi^0$ , or  $\gamma$  that differentiates the eight different modes contributes negligibly to the  $\Delta E$  resolution.

TABLE VI. The  $B$  meson candidate angular selection criteria.

Decay mode	$ \cos \theta_B $	$ \cos \theta_S $	$ \cos \theta_H $
$B^+ \rightarrow D_s^+ \bar{D}^0$	$\leq 0.75$	$\leq 0.95$	-
$B^+ \rightarrow D_s^{*+} \bar{D}^0$	$\leq 0.75$	$\leq 0.95$	$\leq 0.80$
$B^+ \rightarrow D_s^+ \bar{D}^{*0}$	$\leq 0.75$	$\leq 0.95$	$\geq 0.35$
$B^+ \rightarrow D_s^{*+} \bar{D}^{*0}$	$\leq 0.85$	$\leq 0.95$	-
$B^0 \rightarrow D_s^+ D^-$	$\leq 0.75$	$\leq 0.95$	-
$B^0 \rightarrow D_s^{*+} D^-$	$\leq 0.85$	$\leq 0.95$	$\leq 0.80$
$B^0 \rightarrow D_s^+ D^{*-}$	$\leq 0.85$	-	$\geq 0.35$
$B^0 \rightarrow D_s^{*+} D^{*-}$	-	-	-

and width from the fit to the sum of all modes are consistent with those obtained from the Monte Carlo simulation. The total in the peak is  $171 \pm 18$  events.

The beam-constrained mass plots for the individual  $B^0$  and  $B^+$  decay channels are shown in Figs. 7 and 8. The mass and width for these fits are fixed to the value obtained from the fit to the sum of all the modes.

The branching fractions are calculated as<sup>3</sup>

$$\mathcal{B}(B \rightarrow D_s^{(*)+} \bar{D}^{(*)}) = \frac{1}{N_{B\bar{B}}} \frac{N_{D_s^{(*)+} \bar{D}^{(*)}}}{\sum_i \sum_j \mathcal{B}_i \mathcal{B}_j \varepsilon_{ij}}, \quad (2)$$

where  $N_{B\bar{B}}$  is the number of  $B\bar{B}$  pairs,  $N_{D_s^{(*)+} \bar{D}^{(*)}}$  is the number of signal events extracted from the fit to the beam-constrained mass distribution,  $\mathcal{B}_i$  is the branching fraction of the  $i$ th charm decay mode, and  $\varepsilon_{ij}$  is the reconstruction efficiency for the combination of the  $i$ th  $D_s^+$  decay channel and the  $j$ th  $\bar{D}$  decay channel [15]. The resulting exclusive branching fractions are listed in Table VII where the first error is the statistical error, the second error is the systematic error from all sources other than the uncertainty in the normalizing branching fractions,  $\mathcal{B}(D_s^+ \rightarrow \phi \pi^+)$  and  $\mathcal{B}(D^0 \rightarrow K^- \pi^+)$ , and the third error is that due to the uncertainty in the normalizing branching fractions, which is completely dominated by the uncertainty in  $\mathcal{B}(D_s^+ \rightarrow \phi \pi^+)$ .

The systematic errors associated with the uncertainty in the detection efficiencies of charged tracks and neutral clusters are calculated in the following manner. A tracking efficiency error of 2% per track is assumed except for the ‘‘slow’’  $\pi^+$  from  $D^{*+} \rightarrow D^0 \pi^+$  decays where an additional 4.6% is added in quadrature (making the total systematic error for the slow pion to be 5%). This additional error arises because the tracking efficiency is rising sharply at low momentum. The tracking errors add linearly except for the additional 4.6% on the slow pion. For example, for the  $D^{*+} \rightarrow D^0 \pi^+$ ,  $D^0 \rightarrow K^- \pi^+ \pi^+ \pi^-$  decay chain, the systematic error associated with tracking is  $\sqrt{(5 \times 2)^2 + 4.6^2} = 11\%$ . The systematic errors associated with neutrals, 3% per photon and 5% per  $\pi^0$  or  $\eta$ , are also added linearly. The charged and neutral systematic errors are then added in quadrature. The total systematic error due to uncertainties in efficiencies is then the weighted average of the systematic errors of the particular decay channels where

<sup>3</sup>Equal production of charged and neutral  $B$  mesons is assumed.

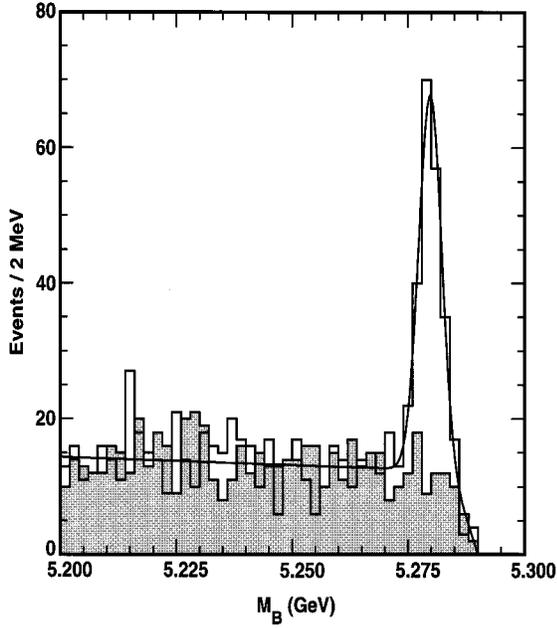

FIG. 6. The beam-constrained mass for the sum of the eight  $B \rightarrow D_s^{(*)+} \bar{D}^{(*)-}$  modes. The solid histogram is the data within the  $\Delta E$  signal window while the filled histogram is the data in the  $\Delta E$  sidebands (as described in the text). The curve is the result of the fit described in the text.

the weight is  $\varepsilon \cdot \mathcal{B}$  for that particular decay channel. The systematic error due to the uncertainties in the relative branching fractions is calculated in the same manner. These are the two dominant sources of systematic error.

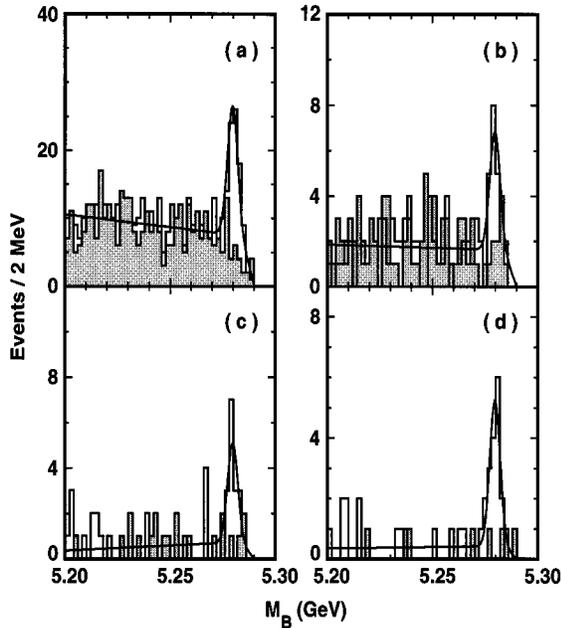

FIG. 7. The beam-constrained mass plots for the  $B^+$  decay modes: (a)  $D_s^+ \bar{D}^0$ , (b)  $D_s^{*+} \bar{D}^0$ , (c)  $D_s^+ \bar{D}^{*0}$ , and (d)  $D_s^{*+} \bar{D}^{*0}$ . The solid histogram is the data within the  $\Delta E$  signal window while the filled histogram is the data in the  $\Delta E$  sidebands (as described in the text). The curve is the result of the fit described in the text.

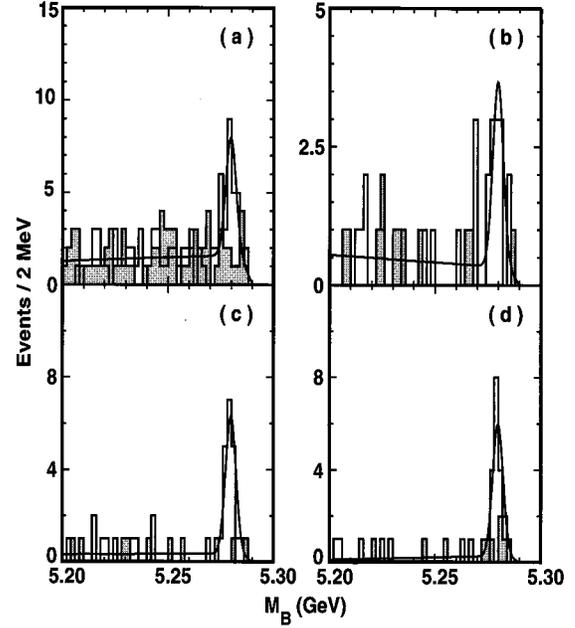

FIG. 8. The beam-constrained mass plots for the  $B^0$  decay modes: (a)  $D_s^+ D^-$ , (b)  $D_s^{*+} D^-$ , (c)  $D_s^+ D^{*-}$ , and (d)  $D_s^{*+} D^{*-}$ . The solid histogram is the data within the  $\Delta E$  signal window while the filled histogram is the data in the  $\Delta E$  sidebands (as described in the text). The curve is the result of the fit described in the text.

The other possible sources of systematic error which were investigated include: cross-feed between the eight channels, uncertainty in the efficiency due to the method of choosing the candidate with the smallest  $|\Delta E|$ , parametrization of the background in the beam-constrained mass plots, and particle identification requirements. There is a non-negligible contribution to the systematic error due to the background parametrization for the  $B \rightarrow D_s^+ \bar{D}$  modes where the background in the beam-constrained mass plot is significant.

## V. THE $B \rightarrow D_s^{(*)+} \bar{D}^{(*)-}$ DECAY RATES

In the dominant process leading to a two-body decay of the type  $B \rightarrow D_s^{(*)+} D^{(*)-}$ , shown in Fig. 1, the  $D_s^{(*)+}$  is produced from the fragmentation of the  $W^+$ . The analogous  $b \rightarrow u$  transitions lead to final states like  $D_s^+ \pi^-$  but these decay rates are down by roughly  $|V_{ub}/V_{cb}|^2 \approx 0.006$  compared to  $b \rightarrow c$  transitions [16,17]. A  $D_s^+$  is not produced in internal  $W^+$  decay. The decay  $B \rightarrow D_s^{(*)+} \bar{D}^{(*)-}$  can also proceed through the ‘‘penguin’’ decay mode  $\bar{b} \rightarrow \bar{s} g, g \rightarrow c \bar{c}$  but this is expected to be small. Other processes, such as annihilation and  $W$ -exchange, lead to final states like  $D_s^+ K^{(*)-}$  but there is no evidence that these processes are significant in  $B$  meson decay [16,17]. None of these scenarios leads to a significant difference in the charged and neutral  $B \rightarrow D_s^{(*)+} \bar{D}^{(*)-}$  decay rates.

The equivalence of the charged and neutral decay rates can be tested using the exclusive branching fractions and  $\tau(B^+)/\tau(B^0) \equiv \tau_{+/0} = 0.98 \pm 0.09$  [6]. The results are given in Table VIII where, for a given decay mode (e.g.,  $B \rightarrow D_s^+ \bar{D}^{*0}$ ),  $\mathcal{B}^{+(0)}$  denotes the branching fraction for the charged (neutral)  $B$  to decay via this mode. Most of the

TABLE VII. The efficiency times charmed and noncharmed branching fractions ( $\varepsilon \cdot \mathcal{B}$ ), the number of reconstructed events, and the measured branching fractions for each of the eight  $B$  decay channels. The quoted error on  $\varepsilon \cdot \mathcal{B}$  is just that due to Monte Carlo statistics. The error on the number of events is purely statistical. The third errors in the branching fractions after the statistical and systematic errors is the 11% uncertainty in  $\mathcal{B}(D_s^+ \rightarrow \phi \pi^+)$  which is common to all measurements.

Decay channel	$\varepsilon \cdot \mathcal{B} (10^{-3})$	No. events	Branching fraction (%)
$B^+ \rightarrow D_s^+ \bar{D}^0$	$2.041 \pm 0.008$	$58.4 \pm 10.0$	$1.26 \pm 0.22 \pm 0.25 \pm 0.15$
$B^+ \rightarrow D_s^{*+} \bar{D}^0$	$0.826 \pm 0.03$	$16.1 \pm 5.0$	$0.87 \pm 0.27 \pm 0.17 \pm 0.10$
$B^+ \rightarrow D_s^+ \bar{D}^{*0}$	$0.425 \pm 0.002$	$13.5 \pm 4.1$	$1.40 \pm 0.43 \pm 0.35 \pm 0.17$
$B^+ \rightarrow D_s^{*+} D^{*0}$	$0.211 \pm 0.001$	$14.9 \pm 4.2$	$3.10 \pm 0.88 \pm 0.65 \pm 0.37$
$B^0 \rightarrow D_s^+ D^-$	$1.031 \pm 0.007$	$19.7 \pm 5.5$	$0.87 \pm 0.24 \pm 0.20 \pm 0.10$
$B^0 \rightarrow D_s^{*+} D^-$	$0.470 \pm 0.003$	$10.3 \pm 3.6$	$1.00 \pm 0.35 \pm 0.22 \pm 0.11$
$B^0 \rightarrow D_s^+ D^{*-}$	$0.868 \pm 0.003$	$18.4 \pm 4.5$	$0.93 \pm 0.23 \pm 0.16 \pm 0.11$
$B^0 \rightarrow D_s^{*+} D^{*-}$	$0.384 \pm 0.002$	$17.7 \pm 4.4$	$2.03 \pm 0.50 \pm 0.36 \pm 0.24$

systematic errors cancel when calculating  $\mathcal{B}^0/\mathcal{B}^+$  except for the 10% uncertainty in  $\mathcal{B}(D^+ \rightarrow K^- \pi^+ \pi^+)/\mathcal{B}(D^0 \rightarrow K^- \pi^+)$  [12] and the 7% error in the  $\pi^0/\pi^+$  efficiencies [18] which comes in directly when taking the ratios of modes involving  $D^{*0}$  and  $D^{*+}$  mesons. The mean value of  $\Gamma(B^0 \rightarrow D_s^{(*)+} D^{(*)-})/\Gamma(B^+ \rightarrow D_s^{(*)+} \bar{D}^{(*)0})$  of  $0.69 \pm 0.13 \pm 0.11$  is not inconsistent with the decay rates for the charged and neutral  $B$  mesons being equal.

Assuming that the charged and neutral decay rates are equal, and that  $\tau_{+0}=1$ , it is reasonable to calculate the average branching fractions. For a particular  $B \rightarrow D_s^{(*)+} \bar{D}^{(*)}$  decay channel, the yield is extracted from a fit to the sum of the  $B^0 \rightarrow D_s^{(*)+} D^{(*)-}$  and  $B^+ \rightarrow D_s^{(*)+} \bar{D}^{(*)0}$  beam-constrained mass distributions. The average branching fraction is then calculated as in Eq. (2). The results are given in Table VIII.

## VI. FACTORIZATION AND PREDICTIONS FOR TWO-BODY RATES

Predictions for exclusive branching fractions have been made using the factorization ansatz. This method was pioneered by Bauer, Stech, and Wirbel (BSW) [19]. Any calculation of widths using factorization arrives at an equation of the form

$$\mathcal{B}(B \rightarrow D_s^{(*)+} \bar{D}^{(*)}) = K G_F^2 a_1^2 |V_{cb} V_{cs}^*|^2 f_{D_s^{(*)}}^2 F_{(*)}^2 \tau_B, \quad (3)$$

where  $K$  is a kinematic factor and  $F_{(*)}$  is the form factor term (summed over polarizations for decays involving  $D^{*}$

mesons, etc.). The factorization parameter  $a_1$  is the relevant one for external spectator decays. The difference between the predictions comes from the form factor term. Bauer, Stech, and Wirbel (BSW) use a simple pole form while other calculations [20–24] use form factors motivated by heavy quark effective theory (HQET) [25]. Several predictions along with the measured average branching fractions are given in Table IX.

While there are significant differences between the predictions for any particular branching fraction, the variations in the predictions for the ratios of the decay widths due to the different parametrizations of the form factors are smaller. These predictions are given in Table X. The decay constant dependence is given explicitly in Table X although, in the heavy quark limit, the vector and pseudoscalar decay constants are equal. More precisely,  $f_{\bar{p}}^2 = f_V^2 = 12 |\Psi(0)|^2 / M$  where  $|\Psi(0)|$  is the wave function of the light antiquark and heavy quark at zero relative separation, and  $M$  is the heavy-meson mass [21]. As can be seen in Table X, taking  $f_{D_s^{*+}} = f_{D_s^+}$ , the  $B \rightarrow D_s^{*+} \bar{D}$  and  $B \rightarrow D_s^+ \bar{D}^*$  widths are predicted to be roughly equal. It was assumed in [19] that  $(f_{D_s^{*+}}/f_{D_s^+})^2 = 1.86$  leading to their prediction that  $\Gamma(B \rightarrow D_s^{*+} \bar{D})$  is some 2.5 times larger than  $\Gamma(B \rightarrow D_s^+ \bar{D}^*)$ .

The experimental results for the ratios of widths are given in the last row of Table X. The quoted error is the sum of the statistical and systematic errors added in quadrature. Most of the experimental systematic errors cancel except the contribution due to an extra slow  $\pi$  or  $\gamma$  in, for example,

TABLE VIII. The ratio of charged and neutral decay rates and the average  $B \rightarrow D_s^{(*)+} \bar{D}^{(*)}$  branching fractions. Equal charged and neutral  $B$  meson production rates are assumed.

Decay mode	$(\mathcal{B}^0/\mathcal{B}^+)(\tau_{B^+}/\tau_{B^0}) = \Gamma^0/\Gamma^+$	Average branching fraction (%)
$B \rightarrow D_s^+ \bar{D}$	$0.68 \pm 0.22 \pm 0.10$	$1.10 \pm 0.17 \pm 0.28 \pm 0.13$
$B \rightarrow D_s^{*+} \bar{D}$	$1.13 \pm 0.53 \pm 0.18$	$0.89 \pm 0.21 \pm 0.20 \pm 0.10$
$B \rightarrow D_s^+ \bar{D}^*$	$0.65 \pm 0.25 \pm 0.09$	$1.12 \pm 0.21 \pm 0.26 \pm 0.13$
$B \rightarrow D_s^{*+} \bar{D}^*$	$0.65 \pm 0.25 \pm 0.09$	$2.41 \pm 0.45 \pm 0.51 \pm 0.29$

TABLE IX. Predictions for the  $B \rightarrow D_s^{(*)+} \bar{D}^{(*)}$  branching fractions assuming  $|V_{cs}|=0.974$ ,  $f_{D_s}=f_{D_s^*}=280$  MeV,  $V_{cb}=0.038$ ,  $\tau_B=1.52$  ps, and  $|a_1|=1.07$  [14], which was derived from  $B^0 \rightarrow D^{(*)+} \pi^-/\rho^-$  decays. The CLEO II values are the values of Table VIII with all of the errors added in quadrature.

Model	$D_s^+ \bar{D}$	$D_s^{*+} \bar{D}$	$D_s^+ \bar{D}^*$	$D_s^{*+} \bar{D}^*$
BSW [19]	1.69	0.99	0.76	2.74
Neubert <i>et al.</i> [20]	1.25	1.07	1.03	2.76
Du and Liu [22]	1.70	1.14	1.26	3.10
Deandrea <i>et al.</i> [23]	1.21	0.83	0.85	3.17
Mannel <i>et al.</i> [24]	0.88	0.56	0.56	1.70
CLEO II	$1.10 \pm 0.35$	$0.89 \pm 0.31$	$1.12 \pm 0.36$	$2.41 \pm 0.74$

$B \rightarrow D_s^{*+} \bar{D}/B \rightarrow D_s^+ \bar{D}$ , and the addition of the uncertainty in the  $D^+$  branching fraction scale in  $\mathcal{B}(B \rightarrow D_s^{(*)+} \bar{D})$ . The data favor the prediction that  $f_{D_s}=f_{D_s^*}$ . The BSW predictions for the ratios of widths, where the pole form for the form factors is used, are excluded by the experimental result for  $\mathcal{B}(B \rightarrow D_s^+ \bar{D})/\mathcal{B}(B \rightarrow D_s^+ \bar{D}^*)$ , while the predictions using HQET motivated form factors describe the data well. This is one of the few comparisons of theory with the data that is insensitive to the large uncertainty in  $\mathcal{B}(D_s^+ \rightarrow \phi \pi^+)$ .

## VII. FIT TO THE INCLUSIVE $D_s^+$ MOMENTUM SPECTRUM

Since the  $B$  mesons are produced nearly at rest, the two-body decays result in  $D_s^{(*)+}$  momentum spectra which are flat distributions, about 300 MeV wide, around the decay momentum. The  $D_s^{*+}$  decays predominantly to  $D_s^+ \gamma$  while the  $P$ -wave  $c\bar{s}$  mesons, the  $D_{s1}^+(2536)$  and  $D_{s2}^{*+}(2573)$ , [28] decay only to  $D^{(*)}K$ . Therefore,  $B \rightarrow D_s^{*+} X$  decays contribute to the inclusive  $D_s^+$  momentum spectrum with distributions which are slightly broadened and shifted down in momentum from the corresponding  $B \rightarrow D_s^+ X$  decay while the other  $c\bar{s}$  resonances do not contribute to the inclusive  $D_s^+$  momentum spectrum.

There are two basic mechanisms giving three-body final states. Events of the type  $B \rightarrow D_s^{(*)+} \bar{D}^{(*)} X$  are produced via

the external spectator diagram of Fig. 1 but with the popping of an additional  $q\bar{q}$  pair. A  $D_s^-$  can be produced in  $B$  meson decay when an  $s\bar{s}$  is produced and the  $s$  quark combines with the anticharm quark from the decay of the  $\bar{b}$  quark. These two three-body mechanisms are referred to as ‘‘upper-vertex’’ and ‘‘lower-vertex’’ three-body decays, respectively. The correlation between the charge of the  $D_s^\pm$  with that of the  $B$  has not been exploited in the analysis of the inclusive  $D_s^+$  momentum spectrum because the flavor of the  $B$  which produced the  $D_s^\pm$  is not measured [31].

The function used in the fit to the inclusive  $D_s^+$  momentum spectrum includes contributions from the following sources.

(A)  $B \rightarrow D_s^{(*)+} \bar{D}^{(*)}$  decays. This is the only contribution where the relative branching fractions of the individual contributing channels are known. The predictions and measurements are given in Table X. It is assumed that  $f_{D_s}=f_{D_s^*}$ . A fit is done for each of the predictions of Table X and the variation in the result is taken as the systematic error due to model dependence.

(B)  $B \rightarrow D_s^{(*)+} D^{**}$  decays. Only the narrow  $P$ -wave charmed states, the  $D_1(2420)$  and  $D_2^*(2460)$ , are used. The contributions from  $B \rightarrow D_s^+ \bar{D}_1(2420)$ ,  $B \rightarrow D_s^{*+} \bar{D}_1(2420)$ ,  $B \rightarrow D_s^+ \bar{D}_2^*(2460)$ , and  $B \rightarrow D_s^{*+} \bar{D}_2^*(2460)$  are added with equal weight. The broad, not yet observed,  $0^+$  and  $1^+$  states are assumed to be taken into account by the three-body or ‘‘nonresonant’’ part of the function described next.

TABLE X. Predictions for ratios of widths in  $B \rightarrow D_s^{(*)+} \bar{D}^{(*)}$  decays.

Model	$\frac{\Gamma(B \rightarrow D_s^{*+} \bar{D})}{\Gamma(B \rightarrow D_s^+ \bar{D}^*)}$	$\frac{\Gamma(B \rightarrow D_s^+ \bar{D})}{\Gamma(B \rightarrow D_s^+ \bar{D}^*)}$	$\frac{\Gamma(B \rightarrow D_s^{*+} \bar{D}^*)}{\Gamma(B \rightarrow D_s^+ \bar{D}^*)}$
BSW [19]	$1.31(f_{D_s^*}/f_{D_s})^2$	2.24	2.77
Rosner [21]	$1.00(f_{D_s^*}/f_{D_s})^2$	1.43	2.59
Neubert <i>et al.</i> [20]	$1.04(f_{D_s^*}/f_{D_s})^2$	1.47	2.56
Du and Liu [22]	$0.91(f_{D_s^*}/f_{D_s})^2$	1.35	2.72
Deandrea <i>et al.</i> [23]	$0.97(f_{D_s^*}/f_{D_s})^2$	1.42	3.84
Mannel <i>et al.</i> [24]	$1.00(f_{D_s^*}/f_{D_s})^2$	1.56	3.01
CLEO II	$0.80 \pm 0.24$	$0.99 \pm 0.24$	$2.70 \pm 0.81$

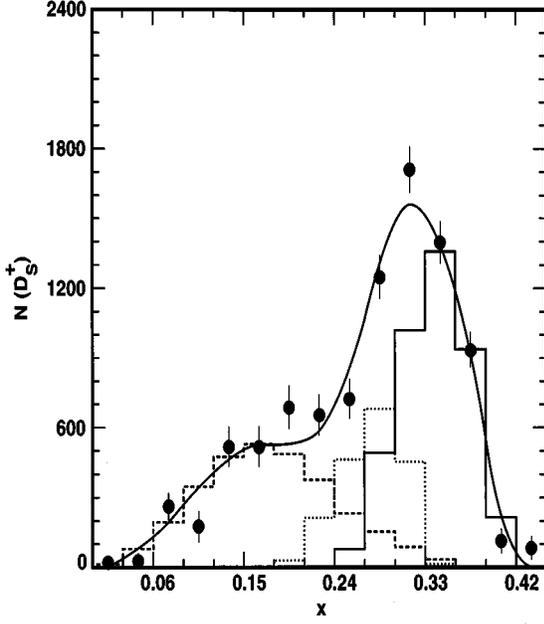

FIG. 9. An example of a fit to the  $D_s^+$  momentum spectrum. The data are the points with error bars and the smooth curve is the result of the fit. The histograms are the components of the fitting function as described in the text where the solid histogram is (A), the  $D_s^{(*)+}\bar{D}^{(*)}$  component; the dotted histogram is (B), the  $D_s^{(*)+}\bar{D}^{**}$  component; and the dashed histogram is (C), the  $D_s^{(*)+}\bar{D}^{(*)}\pi/\rho$  component.

(C) Upper-vertex  $B \rightarrow D_s^{(*)+}\bar{D}^{(*)}\pi/\rho/\omega$  decays. Both the relative amounts of each particle type in these decays and the shape of the resultant  $D_s^+$  momentum spectrum are unknown. The individual shapes are generated according to phase space alone and are added with equal weight.

(D) Lower-vertex decays. As in (C), the shapes are generated according to phase space while the relative branching fractions (e.g.,  $D_s^- K^+ \pi^+$  vs  $D_s^{*-} K^{*0} \pi^+$ ) are arbitrary. Lower-vertex decays are expected to be suppressed and are measured to be small [16,31]. This is the only component of the fitting function which contributes  $D_s^+$  mesons in the  $x > 0.41$  region.  $D_s^+$  mesons with  $x > 0.41$  can be produced in  $b \rightarrow u$  transitions, and by annihilation and  $W$ -exchange diagrams, but these components are known to be small [16,17] and are not included in the fit.

As an example, the result of the fit using the ratios of  $B \rightarrow D_s^{(*)+}\bar{D}^{(*)}$  widths from [20] is shown in Fig. 9.

The ratio of the sum of the four  $B \rightarrow D_s^{(*)+}\bar{D}^{(*)}$  rates to the total inclusive rate is found to be  $(45.7 \pm 1.9 \pm 3.7 \pm 0.6)\%$  where the first error is statistical, the second is the systematic error, and the last error represents the model uncertainty. ARGUS and CLEO-1.5 mea-

sured this ratio to be  $(58 \pm 7 \pm 9)\%$  and  $(56 \pm 10)\%$ , respectively [7,8]. The systematic error is dominated by the uncertainty in the shapes of the spectra included in the fitting function. There is no contribution to the systematic error from either the uncertainty in  $\mathcal{B}(D_s^+ \rightarrow \phi \pi^+)$  or the uncertainty in the tracking efficiency. The contributions to the systematic error due to uncertainty in the shape of the continuum  $D_s^+$  momentum spectrum and due to the uncertainty in the  $x$  dependence of the detection efficiency were found to be negligible.

Several methods were used to estimate the systematic error due to the uncertainty in the shapes of the spectra used in the fit. The fit was repeated for various combinations of (B), (C), and (D) with (A). The inclusive  $D_s^+$  momentum spectrum cannot be fit with a function consisting only of (A) and (D) or (A) and (B). In all cases, the spectrum due to lower-vertex decays (D), is found to contribute a negligible amount to the total inclusive rate. The  $D_s^+$  yield in the  $0.4 < x < 0.5$  region is consistent with continuum background. The fit was also repeated allowing (C) to have three components characterized by how ‘hard’ the constituent spectra were. If  $B \rightarrow D_s^+ \bar{D} \pi$  is the dominant decay mode of the twelve modes comprising (C), then the spectrum can be fit requiring little or no contribution from (B). Therefore, it is not possible at present to extract from a fit to the inclusive  $D_s^+$  momentum spectrum a meaningful number for any, or even the sum, of the  $B \rightarrow D_s^{(*)+}\bar{D}^{**}$  branching fractions.

Using the result of the fit to the inclusive  $D_s^+$  momentum spectrum for the fraction of the  $B \rightarrow D_s^{(*)+}\bar{D}^{(*)}$  rates to the inclusive rate and the value for the inclusive branching fraction gives  $\sum \mathcal{B}(B \rightarrow D_s^{(*)+}\bar{D}^{(*)}) = (5.53 \pm 0.23 \pm 0.56 \pm 0.63)\%$  where the first error is statistical, the second is the systematic error, and the third is the error due to the uncertainty in the  $D_s^+ \rightarrow \phi \pi^+$  branching fraction. This compares well with the statistically less precise value of  $\sum \mathcal{B}(B \rightarrow D_s^{(*)+}\bar{D}^{(*)}) = (5.52 \pm 0.57 \pm 1.35 \pm 0.63)\%$  which is derived by summing the average branching fractions given in Table VIII.

## VIII. EXTRACTION OF THE $D_s^+$ DECAY CONSTANT

The factorization hypothesis, Eq. (3), can be used to extract a value for the  $D_s^+$  decay constant from the measured  $B \rightarrow D_s^{(*)+}\bar{D}^{(*)}$  branching fractions and experimental information on  $a_1$ ,  $V_{cb}$ , and  $\tau_B$ . Unfortunately, there are large variations in the theoretical predictions for any particular  $B \rightarrow D_s^{(*)+}\bar{D}^{(*)}$  branching fraction. The parameter  $a_1$  has been derived from  $B \rightarrow D^{(*)}\pi$  branching fraction measurements [14] but there are at least some theoretical reasons for expecting  $a_1$  to have different values depending on whether the  $W^+$  fragments to  $u\bar{d}$  or  $c\bar{s}$  [20,32,33].

Some theoretical and experimental errors cancel in the ratio

$$\frac{\Gamma(B \rightarrow \bar{D}^* D_s^{(*)+})}{d\Gamma(B \rightarrow \bar{D}^* e^+ \nu_e)/dq^2|_{q^2=m_{D_s^{(*)}}^2}} = 6\pi^2 (a_1^{c\bar{s}})^2 \delta^{(*)} f_{D_s^{(*)}}^2 |V_{cs}|^2, \quad (4)$$

where  $\delta=0.39$  and  $\delta^*=1.0$  for  $B\rightarrow D_s^+\bar{D}^*$  and  $B\rightarrow D_s^{*+}\bar{D}^*$  decays, respectively.<sup>4</sup>

It was found in [18] that

$$\frac{d\Gamma(B\rightarrow\bar{D}^*e^+\nu_e)}{dq^2}\Big|_{q^2=m_{D_s}^2}=3.17\pm 0.16\pm 0.13\pm 0.14\pm 0.34\text{ ns}^{-1}\text{ GeV}^{-2},$$

and

$$\frac{d\Gamma(B\rightarrow\bar{D}^*e^+\nu_e)}{dq^2}\Big|_{q^2=m_{D_s^*}^2}=3.33\pm 0.16\pm 0.14\pm 0.15\pm 0.34\text{ ns}^{-1}\text{ GeV}^{-2},$$

where the first error is statistical, the second is the error due to the uncertainty in the  $D$  and  $D^*$  branching fractions, the third is due to the uncertainty in  $\tau(B^+)/\tau(B^0)$ , and the last is the systematic error associated with detection efficiencies.

Using the average branching fractions, the decay constants are found to be

$$a_1f_{D_s}=319\pm 31\pm 32\pm 18\text{ MeV},$$

$$a_1f_{D_s^*}=286\pm 28\pm 26\pm 16\text{ MeV},$$

where the first error is statistical and the second is the systematic error which includes the uncertainties in the relative  $D$  and  $D_s^+$  branching fractions, and the last is the uncertainty in the  $\mathcal{B}(D_s^+\rightarrow\phi\pi^+)$ . Averaging the two results under the assumption that  $f_{D_s}=f_{D_s^*}$  gives

$$a_1f_{D_s}=300\pm 21\pm 30\pm 17\text{ MeV}.$$

A value for  $f_{D_s}$  requiring a ratio of the form factors can be obtained using ratios of hadronic rates such as

$$\frac{\Gamma(B\rightarrow\bar{D}D_s^+)}{\Gamma(B^0\rightarrow D^-\pi^+)}=KR_{a_1}^2\frac{f_{D_s}^2}{f_\pi^2}\frac{|V_{cs}|^2}{|V_{ud}|^2}\frac{|\xi(q^2=m_{D_s}^2)|^2}{|\xi(q^2=m_\pi^2)|^2},\quad (5)$$

where  $K$  is a calculable kinematic factor and  $R_{a_1}\equiv a_1^{c\bar{s}}/a_1^{u\bar{d}}$ , with the superscript of  $a_1$  referring to the  $W^+$  fragmentation mode.<sup>5</sup> Note that only  $B^0$  decays can be used in the denominator since the corresponding  $B^+$  decay can proceed through both internal and external  $W^+$  emission.

The branching fractions extracted from the fit to the inclusive  $D_s^+$  momentum spectrum, rather than the results from the full reconstruction, are used because this results in smaller statistical and systematic errors. Using them also gives a good measure of the model dependence since the same form factor parametrization is used for the calculations of both the ratios of  $B\rightarrow D_s^{(*)+}\bar{D}^{(*)}$  widths used in the inclusive fit and Eq. (4). The systematic error due to form

factor parametrization can then be quantified by examining the spread in  $f_{D_s}$  results derived using the different models. Since, for any particular model, it is the sum of the  $B\rightarrow D_s^{(*)+}\bar{D}^{(*)}$  branching fractions which results from the fit to inclusive  $D_s^+$  momentum spectrum, the ratio  $R_{\text{exp}}\equiv\Sigma\mathcal{B}(B\rightarrow D_s^{(*)+}\bar{D}^{(*)})/\Sigma\mathcal{B}(B^0\rightarrow\pi^+\rho^+D^{(*)-})$  is used, where the denominator is calculated using CLEO measurements [14]. This is compared to the theoretical predictions for the same quantity (call it  $R_{\text{th}}$ ) to extract  $f_{D_s}$ . It is assumed that  $f_{D_s}=f_{D_s^*}$ . The  $\bar{u}d$  decay constants are  $f_\pi=131.74\pm 0.15\text{ MeV}$  and  $f_\rho=205\pm 10\text{ MeV}$  [20].

The results of such an analysis are shown in Table XI. Only the  $R_{\text{exp}}$  values obtained using HQET motivated form factors were included. The average value is

$$R_{a_1}f_{D_s}=288\pm 13\pm 28\pm 16\pm 20\text{ MeV},$$

where the first error is statistical, the second is the systematic error including the uncertainty in the relative charm branching fractions, the third error is due to the uncertainty in  $\mathcal{B}(D_s^+\rightarrow\phi\pi^+)$ , and the final error reflects the model uncertainty. This last error is conservatively taken to be the largest deviation from the mean between the different model predictions.

These results for  $f_{D_s}$  are consistent with the value obtained by CLEO using  $D_s^+\rightarrow\mu^+\nu$  decays [34], as shown in Table XII.

## IX. CONCLUSIONS

The result for the inclusive  $B\rightarrow D_s^+X$  branching fraction is

$$\mathcal{B}(B\rightarrow D_s^+X)=(12.11\pm 0.39\pm 0.88\pm 1.38)\%,$$

TABLE XI. The experimental and theoretical values for  $R$ , which is defined as  $\Sigma\Gamma(B\rightarrow D_s^{(*)+}\bar{D}^{(*)})/\Sigma\Gamma(B^0\rightarrow\pi^+\rho^+D^{(*)-})$ , and the resulting  $f_{D_s}$  values.

Model	$R_{\text{th}}(\text{GeV}^2)$	$R_{\text{exp}}$	$f_{D_s}(\text{MeV})$
Neubert <i>et al.</i>	$35.33f_{D_s}^2$	$2.68\pm 0.23$	$275\pm 12\pm 25$
Du and Liu	$28.12f_{D_s}^2$	$2.67\pm 0.23$	$308\pm 13\pm 28$
Deandrea <i>et al.</i>	$37.49f_{D_s}^2$	$2.80\pm 0.24$	$273\pm 12\pm 22$
Mannel <i>et al.</i>	$30.81f_{D_s}^2$	$2.72\pm 0.23$	$297\pm 13\pm 23$

<sup>4</sup>The analysis in [35] did not include any QCD corrections (i.e.,  $a_1$ ). The kinematic factor  $\delta$  is calculated to be 0.41 in [35] and 0.39 in [20]. It is shown in [20] that  $\delta\rightarrow 0.37$  in the limit of infinitely heavy quarks.

<sup>5</sup>In all of the calculations discussed in this paper,  $R_{a_1}$  was assumed to equal 1.

TABLE XII. Determinations of  $f_{D_s}$ . The first error is statistical while the second is the systematic error. A  $D_s^+ \rightarrow \phi \pi^+$  branching fraction of  $(3.5 \pm 0.4)\%$  is common to all results and the uncertainty in  $\mathcal{B}(D_s^+ \rightarrow \phi \pi^+)$  is not included in the systematic error. Factorization and  $f_{D_s} = f_{D_s^*}$  are assumed in the derivations of the values in this paper, given in rows 2 and 3. An  $a_1$  value of  $1.07 \pm 0.04 \pm 0.06$  [14] was used to get  $f_{D_s}$  from the ratio of the hadronic to semileptonic widths. For the  $f_{D_s}$  value obtained from the ratios of hadronic widths, it is again assumed that  $a_1$  is independent of whether the  $W^+$  fragments to  $\bar{u}d$  or  $\bar{c}s$ .

Technique	$f_{D_s}$ (MeV)
$D_s^+ \rightarrow \mu^+ \nu_\mu$	$284 \pm 30 \pm 30$
$\Gamma(B \rightarrow D_s^{(*)+} \bar{D}^{(*)}) / d\Gamma(B \rightarrow \bar{D}^* e^+ \nu_e) / dq^2 _{q^2=m_{D_s^{(*)}}^2}$	$281 \pm 22 \pm 32$
$\Sigma \Gamma(B \rightarrow D_s^{(*)+} \bar{D}^{(*)}) / \Sigma \Gamma(B^0 \rightarrow \pi^+ / \rho^+ D^{(*)-})$	$288 \pm 13 \pm 38$

where the first error is statistical, the second is the systematic error, and the third is the error due to the uncertainty in the  $D_s^+ \rightarrow \phi \pi^+$  branching fraction. It is found from the fit to the inclusive  $D_s^+$  momentum spectrum that the sum of the  $B \rightarrow D_s^{(*)+} \bar{D}^{(*)}$  rates comprises  $(45.7 \pm 1.9 \pm 3.7 \pm 0.6)\%$  of the total inclusive rate, where the last error reflects model dependence. Combining these results gives  $\Sigma \mathcal{B}(B \rightarrow D_s^{(*)+} \bar{D}^{(*)}) = (5.53 \pm 0.23 \pm 0.23 \pm 0.63)\%$ .

The measurements of the  $B \rightarrow D_s^{(*)+} \bar{D}^{(*)}$  branching fractions are given in Table VI. The averages of the  $B^0$  and  $B^-$  branching fractions are

$$\mathcal{B}(B \rightarrow D_s^+ \bar{D}) = (1.10 \pm 0.17 \pm 0.28 \pm 0.13)\%,$$

$$\mathcal{B}(B \rightarrow D_s^{*+} \bar{D}) = (0.89 \pm 0.21 \pm 0.20 \pm 0.10)\%,$$

$$\mathcal{B}(B \rightarrow D_s^+ \bar{D}^*) = (1.12 \pm 0.21 \pm 0.26 \pm 0.13)\%,$$

$$\mathcal{B}(B \rightarrow D_s^{*+} \bar{D}^*) = (2.41 \pm 0.45 \pm 0.51 \pm 0.29)\%,$$

where the first error is statistical, the second error is the systematic error due to the uncertainties in the charmed branching fractions (other than the normalizing modes) and the efficiencies, and the last error is due to the uncertainty in the two normalizing branching fractions,  $\mathcal{B}(D_s^+ \rightarrow \phi \pi^+)$  and  $\mathcal{B}(D^0 \rightarrow K^- \pi^+)$ . This last error is completely dominated by the 11% uncertainty in the  $D_s^+$  branching fraction scale.

Combining these results gives  $\Sigma \mathcal{B}(B \rightarrow D_s^{(*)+} \bar{D}^{(*)}) = (5.52 \pm 0.57 \pm 1.35 \pm 0.63)\%$ , in good agreement with the inclusive  $D_s^+$  analysis.

The ratios of rates calculated using factorization and HQET motivated form factors compare well with the data and favor  $f_{D_s^*} = f_{D_s}$ .

Finally, assuming factorization, the  $D_s^+$  decay constant is extracted from the ratio of the hadronic rate to the semileptonic rate. For  $a_1 = 1.07 \pm 0.04 \pm 0.06$ ,  $f_{D_s}$  is found to be  $281 \pm 22 \pm 32$  MeV where the first error is statistical and the second is the systematic error including the uncertainties in the charm branching fractions. It is found from ratios of hadronic rates that  $f_{D_s} = 288 \pm 13 \pm 32 \pm 20$  MeV where the third error is due to the uncertainty in the form factors.

Three Isgur-Wise functions are examined and  $\sim 15\%$  differences in the predicted branching fractions are found. The median predictions are given in Table IX. The difference between the value given in this paper and those quoted in Table IX is due to the different  $f_{D_s}$  value that was assumed. All three parametrizations of the Isgur-Wise function gave the same ratios of widths.
