Abstract

A series of triazole-containing novobiocin analogues has been designed, synthesized and their inhibitory activity determined. These compounds contain a triazole ring in lieu of the amide moiety present in the natural product. The anti-proliferative effects of these compounds were evaluated against two breast cancer cell lines (SKBr-3 and MCF-7), and manifested activities similar to their amide-containing counterparts. In addition, Hsp90-dependent client protein degradation was observed via western blot analysis, further supporting a common mode of Hsp90 inhibition for both structural classes.

Keywords

Hsp90; Novobiocin; Antiproliferation; Triazole

Current cancer therapy strategies utilize the administration of multiple drug regimens that aim to halt multiple malignant processes simultaneously. Heat shock protein 90 (Hsp90) represents an exciting target for the treatment of cancer, as inhibition of this chaperone can affect multiple proteins that are directly associated with all six hallmarks of cancer.[1−4] Hsp90 is a 90 kDa molecular chaperone and is intimately involved in the post-translational conformational maturation of nascent polypeptides as well as the re-folding of denatured proteins and the re-solubilization of protein aggregates.[5] Pharmacological inhibition of Hsp90 effectively inhibits protein substrates dependent upon Hsp90 for conformational maturation, resulting in destabilization of the Hsp90-client protein heteroprotein complex, which leads to degradation of substrates through the ubiquitin-proteasome pathway.[4,6−7] Many proteins associated with malignant progression; including steroid hormone receptors, transcription factors and protein kinases, rely upon Hsp90 to reach their biologically active, three-dimensional conformation. As such, Hsp90 has emerged as a promising anti-cancer target, with more than 20 clinical trials currently in progress with small molecules that bind the N-terminal ATP binding site.[8]

The Hsp90 protein folding machinery requires co-chaperones and partner proteins to aid in the topological reorientation of polypeptide substrates.[7] This protein folding process is ATP-dependent, with hydrolysis occurring at the N-terminal nucleotide binding site of the Hsp90

homodimer.9 All Hsp90 inhibitors currently in clinical trials bind this region. Although promising data has emerged from these trials, many of these compounds exhibit undesired toxicity and/or complicated dosing schedules. In contrast, the development of Hsp90 inhibitors that target other small molecule binding regions, such as that contained in the C-terminus remains minimally investigated.[10] For example, novobiocin was shown to bind the C-terminus of Hsp90 in 2000 and provided the first example of a small molecule binding site outside of the N-terminus. [11–12] However, novobiocin manifests only modest inhibitory activity (500 µM). Since 2000, other inhibitors of the C-terminus have also been identified, but the development of such compounds has not been thoroughly sought after.[10]

Since the discovery of the Hsp90 C-terminal binding site, analogues of novobiocin have been synthesized and evaluated, with many of the compounds manifesting micromolar antiproliferative activities.[13–17] Modifications to both the coumarin core and benzamide side chain have been pursued, resulting in the production of preliminary structure–activity relationships (SAR). The hydrogen bonding capabilities and the geometry of the amide bond appear to be important for novobiocin binding, however modifications to this moiety have not been fully realized to evaluate SAR. It was proposed that inclusion of 1,2,3-triazoles as a bioisosteric replacement for the amide moiety could facilitate SAR analysis for the aryl side chain by utilizing "click" chemistry. The triazole serves as a bioisostere due to similarities in both electronic and spacial characteristics to the amide bond. In addition, it is metabolically stable to hydrolysis and easily incorporated into small molecules.[18–19] In contrast, triazoles exhibit different hydrogen bonding capabilities and an altered geometry as compared to their amide counterparts, which aids in further elucidation of SAR. For these reasons, a series of 1,2,3-triazole containing novobiocin analogues was prepared. The design, synthesis, and biological evaluation of these compounds are described herein.

Synthesis of the 8-methyl coumarin core, as found in novobiocin, was commenced with commercially available 2-methyl resorcinol, **1** [Scheme 1]. Compound **1** was formylated under Vilsmeier-Haack conditions enlisting $POCl_3$ and DMF, followed by hydrolysis to afford formyl-resorcinol **2**. Similar to the procedure of Sivakumar and co-workers, condensation of **2** with N-acetyl glycine in the presence of acetic anhydride, produced the bis-acylated coumarin, **3**.[20] Deacetylation of both the phenol and amine was accomplished upon heating with HCl and EtOH to afford 3-amino-7-hydroxy-8-methyl-coumarin, **4**. Conversion of amino-coumarin **4** to the azide, which was required for the copper-catalyzed Huisgen 1,3-dipolar cycloaddition, was accomplished by in-situ generation of the 3-diazonium salt upon treatment with sodium nitrite in aqueous acid, followed by the addition of sodium azide to afford 3-azido-coumarin, **5a**.[20] Acetylation of coumarin **5a** was accomplished with acetic anhydride in pyridine to afford **5b**.

Upon the generation of compounds **5a** and **5b**, the copper-catalyzed Huisgen 1,3-dipolar cycloaddition with the corresponding alkynes was set to generate compounds **6–14a** and **6–14b** [Scheme 2]. Standard conditions were used to effect this transformation, and a combination of DMSO and H_2O were found most suitable for optimal product formation. Alkynes **6–10** were chosen to investigate the electronic nature of the aryl side chain, including neutral (Me), electron withdrawing (F) and electron donating (OMe, NMe_2) properties as originally identified during classical novobiocin SAR studies.[13] Alkynes **11–14** were chosen based on prior observations that the analogous amide derivatives manifested good anti-proliferative activities against multiple cell lines,[13] and thus provide direct comparison between amide and triazole analogues.

Completion of the triazole-containing novobiocin analogues was achieved by incorporation of the noviose sugar into **6–14a** [Scheme 3]. The phenols of compounds **6–14a** were noviosylated with the trichloroacetimidate of noviose carbonate (**15**) in the presence of

boron trifluoride etherate.[21] Solvolysis of the cyclic carbonate with methanolic triethylamine afforded novobiocin analogues **6–14c**.

Upon preparation of compounds **6–14 a, b** and **c**, their growth inhibitory activities against MCF-7(ER+) and SKBr-3(ER−, HER2 overexpressing) breast cancer cell lines were determined [Table 1]. These results provide evidence that compounds **14a**, **14b**, **14c**, and **11c** are the most potent analogues prepared in this series. The structure–activity relationships suggest that analogues bearing sterically demanding side chains exhibit greater potency, as compounds with biaryl, indole, or homologated aryl groups (**11–14**) were more efficacious than substituted aryl compounds (**6–10**). In addition, comparison of compounds **6–10** suggests that para-substitution of the aryl ring with Me, OMe, NMe$_2$ or F is not well tolerated, as these compounds displayed minimal anti-proliferative activity. These results suggest that the C-terminal binding pocket has a large hydrophobic pocket that can easily accommodate substituents as in compounds **11–14**.

Additionally, comparision between the amide containing analogues and triazole containing analogues provides further SAR [Table 2]. As evident from the data presented in Table 2, the triazole moiety has little effect on anti-proliferative activity. Both the triazole and amide analogues containing the biaryl and 3-indole side chains indicate the activities for both sets of compounds are comparable against the two cell lines tested. One discrepancy observed between the amide and triazole analogues is that in which simple aryl side chains (**6–10**) manifest IC$_{50}$ values in the 10–20 µM range for the amide–containing molecules while the triazole compounds **6** and **9** display IC$_{50}$ values above 50 µM.[13] These results suggest that the triazole moiety affects biological activity in two ways: the availability of a hydrogen bond donor in the amide linkage and the steric bulk of the side chain. This hydrogen bond contact is lost upon introduction of the triazole moiety, but can be overcome by the introduction of steric bulk in the side chain. A preference for steric bulk has been observed in several series of novobiocin analogues, and appears to be a contributing factor to biological activity.

After analysis of the triazole containing analogues anti-proliferative activity, Western blot analysis was preformed for the most active compound, **14b**, to confirm anti-proliferative activity results from Hsp90 inhibition [Figure 2]. Western blot analysis of MCF-7 cells treated with increasing concentrations of **14b**, induce Hsp90-dependent client protein degradation in a dose-dependent manner, with an apparent IC$_{50}$ value that correlates directly to the anti-proliferative IC$_{50}$ value. Her2 and c-Raf are client proteins of Hsp90, and pharmacological inhibition of Hsp90 leads to their degradation via ubiquitinylation and proteome-mediated hydrolysis. Additionally, compound **14b** appears to have little effect on the heat shock response, as unaltered levels of Hsp90 were observed, consistent with inhibition of the Hsp90 C-terminus. In contrast, client protein degradation and heat shock induction was not observed for the inactive compound **10b** (data not shown). Western blot analysis indicates that these compounds are interfering with the Hsp90-mediated protein folding process, and that the anti-proliferative activities for these compounds are directly related to Hsp90 inhibition.

In conclusion, a series of triazole containing novobiocin analogues was prepared and evaluated against two breast cancer cell lines. Western blot analysis affirmed Hsp90 inhibition by this class of compounds. The compounds described herein exhibit comparable activities to the corresponding amide-containing analogues. These results indicate that the amide moiety can be replaced by the triazole functionality, however, in some cases the loss of the hydrogen bond donor appears detrimental, but can be overcome by the inclusion of steric bulk in the triazole substituent.
