RATE OF CONVERGENCE AND ASYMPTOTIC ERROR DISTRIBUTION OF EULER APPROXIMATION SCHEMES FOR FRACTIONAL DIFFUSIONS

BY YAOZHONG HU$^1$, YAN GHUI LIU AND DAVID NUALART$^2$

University of Kansas

For a stochastic differential equation (SDE) driven by a fractional Brownian motion (fBm) with Hurst parameter $H > \frac{1}{2}$, it is known that the existing (naive) Euler scheme has the rate of convergence $n^{1-2H}$. Since the limit $H \to \frac{1}{2}$ of the SDE corresponds to a Stratonovich SDE driven by standard Brownian motion, and the naive Euler scheme is the extension of the classical Euler scheme for Itô SDEs for $H = \frac{1}{2}$, the convergence rate of the naive Euler scheme deteriorates for $H \to \frac{1}{2}$. In this paper we introduce a new (modified Euler) approximation scheme which is closer to the classical Euler scheme for Stratonovich SDEs for $H = \frac{1}{2}$, and it has the rate of convergence $\gamma_n^{-1}$, where $\gamma_n = n^{2H-1/2}$ when $H < \frac{3}{4}$, $\gamma_n = n/\sqrt{\log n}$ when $H = \frac{3}{4}$ and $\gamma_n = n$ if $H > \frac{3}{4}$. Furthermore, we study the asymptotic behavior of the fluctuations of the error. More precisely, if \{X_t, 0 \leq t \leq T\} is the solution of a SDE driven by a fBm and if \{X^n_t, 0 \leq t \leq T\} is its approximation obtained by the new modified Euler scheme, then we prove that $\gamma_n(X^n - X)$ converges stably to the solution of a linear SDE driven by a matrix-valued Brownian motion, when $H \in (\frac{1}{2}, \frac{3}{4}]$. In the case $H > \frac{3}{4}$, we show the $L^p$ convergence of $n(X^n_t - X_t)$, and the limiting process is identified as the solution of a linear SDE driven by a matrix-valued Rosenblatt process. The rate of weak convergence is also deduced for this scheme. We also apply our approach to the naive Euler scheme.

1. Introduction. Consider the following stochastic differential equation (SDE) on $\mathbb{R}^d$:

\begin{equation}
X_t = x + \int_0^t b(X_s) \, ds + \sum_{j=1}^m \int_0^t \sigma_j^j(X_s) \, dB_s^j, \quad t \in [0, T],
\end{equation}

This is an electronic reprint of the original article published by the Institute of Mathematical Statistics in The Annals of Applied Probability, 2016, Vol. 26, No. 2, 1147–1207. This reprint differs from the original in pagination and typographic detail.
where \( x \in \mathbb{R}^d \), \( B = (B^1, \ldots, B^m) \) is an \( m \)-dimensional fractional Brownian motion (fBm) with Hurst parameter \( H \in (\frac{1}{2}, 1) \) and \( b, \sigma^1, \ldots, \sigma^m : \mathbb{R}^d \to \mathbb{R}^d \) are continuous functions. The above stochastic integrals are pathwise Riemann–Stieltjes integrals. If \( \sigma^1, \ldots, \sigma^m \) are continuously differentiable and their partial derivatives are bounded and locally Hölder continuous of order \( \delta > \frac{1}{H} - 1 \) and \( b \) is Lipschitz, then equation (1.1) has a unique solution which is Hölder continuous of order \( \gamma \) for any \( 0 < \gamma < H \). This result was first proved by Lyons [14], using Young integrals (see [33]) and \( p \)-variation estimates, and later by Nualart and Rascanu [25], using fractional calculus; see [34].

We are interested in numerical approximations for the solution to equation (1.1). For simplicity of presentation, we consider uniform partitions of the interval \([0, T]\), \( t_i = \frac{iT}{n} \), \( i = 0, \ldots, n \). For every positive integer \( n \), we define \( \eta(t) = t_i \) when \( t_i \leq t < t_i + \frac{T}{n} \). The following naive Euler numerical approximation scheme has been previously studied:

\[
X^n_t = x + \int_0^t b(X^n_{\eta(s)}) \, ds + \sum_{j=1}^m \int_0^t \sigma_j(X^n_{\eta(s)}) \, dB^j_s, \quad t \in [0, T].
\]

(1.2)

This scheme can also be written as

\[
X^n_t = X^n_{t_k} + b(X^n_{t_k})(t - t_k) + \sum_{j=1}^m \sigma_j(X^n_{t_k})(B^j_t - B^j_{t_k}),
\]

for \( t_k \leq t < t_{k+1} \), \( k = 0, 1, \ldots, n - 1 \) and \( X^n_0 = x \). It was proved by Mishura [17] that for any real number \( \varepsilon > 0 \) there exists a random variable \( C_\varepsilon \) such that almost surely,

\[
\sup_{0 \leq t \leq T} |X^n_t - X_t| \leq C_\varepsilon n^{1-2H+\varepsilon}.
\]

Moreover, the convergence rate \( n^{1-2H} \) is sharp for this scheme, in the sense that \( n^{2H-1}[X^n_t - X_t] \) converges almost surely to a finite and nonzero limit. This has been proved in the one-dimensional case by Nourdin and Neuenkirch in [18] using the Doss representation of the solution; see also Theorem 10.1 below. Notice that while \( H \) tends to \( \frac{1}{2} \), the convergence rate \( 2H - 1 \) of the numerical scheme (1.2) deteriorates, and so it is not a proper extension of the Euler–Maruyama scheme for the case \( H = \frac{1}{2} \); see, for example, [7, 12]. This is not surprising because the limit \( H \to \frac{1}{2} \) of the SDE (1.1) corresponds to a Stratonovich SDE driven by standard Brownian motion, while the Euler scheme (1.2) is the extension of the classical Euler scheme for the Itô SDEs. It is then natural to ask the following question: Can we find a numerical scheme that generalizes the Euler–Maruyama scheme to the fBm case?
In this paper we introduce the following new approximation scheme that we call a modified Euler scheme:

\[
X^n_t = x + \int_0^t b(X^n_{\eta(s)}) \, ds + \sum_{j=1}^m \int_0^t \sigma^j(X^n_{\eta(s)}) \, dB^j_s
\]

(1.3)

\[+ H \sum_{j=1}^m \int_0^t (\nabla \sigma^j \sigma^j)(X^n_{\eta(s)})(s - \eta(s))^{2H-1} \, ds,\]

or

\[
X^n_t = X^n_{t_k} + b(X^n_{t_k})(t - t_k) + \sum_{j=1}^m \sigma^j(X^n_{t_k})(B^j_t - B^j_{t_k})
\]

\[+ \frac{1}{2} \sum_{j=1}^m (\nabla \sigma^j \sigma^j)(X^n_{t_k})(t - t_k)^{2H},\]

for any \( t \in [t_k, t_{k+1}] \) and \( X^n_0 = x \). Here \( \nabla \sigma^j \) denotes the \( d \times d \) matrix \( (\partial \sigma^j_{i,k}) \) \( 1 \leq i, k \leq d \), and \( (\nabla \sigma^j \sigma^j)^i = \sum_{k=1}^d (\partial \sigma^j_{i,k}) \sigma^j_{k} \).

Notice that if we formally set \( H = \frac{1}{2} \) and replace \( \eta \) by a standard Brownian motion \( W \), this is the classical Euler scheme for the Stratonovich SDE, \( X_t = x + \int_0^t b(X_s) \, ds + \sum_{j=1}^m \sigma^j(X_s) \, dW^j_s \),

In the above and throughout this paper, \( d \) denotes the Stratonovich integral, and \( \delta \) denotes the Itô (or Skorohod) integral.

For our new modified Euler scheme (1.3) we shall prove the following estimate:

\[
\sup_{0 \leq t \leq T} (\mathbb{E}|X_t - X^n_t|)^{1/p} \leq C\gamma_n^{-1},
\]

(1.4)

for any \( p \geq 1 \), where

\[
\gamma_n = \begin{cases} 
  n^{2H-1/2}, & \text{if } \frac{1}{2} < H < \frac{3}{4}, \\
  \frac{n}{\sqrt{\log n}}, & \text{if } H = \frac{3}{4}, \\
  n, & \text{if } \frac{3}{4} < H < 1.
\end{cases}
\]

(1.5)

Note that in (1.4), if we formally set \( H = \frac{1}{2} \), then the convergence rate is \( n^{-1/2} \), which is exactly the convergence rate of the classical Euler–Maruyama
scheme in the Brownian motion case. This suggests that the modified Euler scheme should be viewed as an authentic modified version of the Euler–Maruyama scheme (1.2). The cutoff of the convergence rate for the Euler scheme has already been observed in a simpler context in [19]. The Lévy area corresponds to the simple SDE with $b = 0$, $\sigma^1(x, y) = (1, 0)$, $\sigma^2(x, y) = (0, x)$. In particular, one has $\nabla \sigma^j \sigma^j = 0$, $j = 1, 2$ here, that is, no diagonal noise.

The Levy area corresponds to the simple SDE with $b = 0$, $\sigma^1(x, y) = (1, 0)$, $\sigma^2(x, y) = (0, x)$. In particular, one has $\nabla \sigma^j \sigma^j = 0$, $j = 1, 2$ here, that is, no diagonal noise.

The proof of this result combines the techniques of Malliavin calculus with classical fractional calculus. On the other hand, we make use of uniform estimates for the moments of all orders of the processes $X, X^n$ and their first and second-order Malliavin derivatives, which can be obtained using techniques of fractional calculus, following the approach used, for instance, by Hu and Nualart [8]. The idea of the proof is to properly decompose the error $X_t - X^n_t$ into a weighted quadratic variation term plus a higher order term, that is,

$$X_t - X^n_t = \sum_{i,j=1}^m \sum_{k=0}^{\lfloor nt/T \rfloor} f^{i,j}(t_k) \int_{t_k}^{t_{k+1}} \int_{t_k}^s \delta B_u^i \delta B_j^s + R^n_t,$$

(1.6)

where $\lfloor x \rfloor$ denotes the integer part of a real number $x$. The weighted quadratic variation term provides the desired rate of convergence in $L^p$.

To further study this new scheme and compare it to the classical Brownian motion case, it is natural to ask the following questions: Is the above rate of convergence (1.4) exact or not? Namely, does the quantity $\gamma_n(X_t - X^n_t)$ have a nonzero limit? If yes, how does one identify the limit, and is there a similarity to the classical Brownian motion case (see [10, 13])? In the second part of the paper, we give a complete answer to these questions. The weighted variation term in (1.6) is still a key ingredient in our study of the scheme. As in the Breuer–Major theorem, there is a different behavior in the cases $H \in \left(\frac{1}{2}, \frac{3}{4}\right]$ and $H \in \left(\frac{3}{4}, 1\right)$. If $H \in \left(\frac{1}{2}, \frac{3}{4}\right]$, we show that $\gamma_n(X_t - X^n_t)$ converges stably to the solution of a linear stochastic differential equation driven by a matrix-valued Brownian motion $W$ independent of $B$. The main tools in this case are Malliavin calculus and the fourth moment theorem. We will also make use of a recent limit theorem in law for weighted sums proved in [3]. In the case $H \in \left(\frac{3}{4}, 1\right]$, we show the convergence of $\gamma_n(X_t - X^n_t)$ in $L^p$ to the solution of a linear stochastic differential equation driven by a matrix-valued Rosenblatt process. Again we use the technique of Malliavin calculus and the convergence in $L^p$ of weighted sums, which is obtained applying the approach introduced in [3]. We refer to [20] for a discussion on the asymptotic behavior of some weighted Hermite variations of one-dimensional fBm, which are related with the results proved here.

We also consider a weak approximation result for our new numerical scheme. In this case, the rate is $n^{-1}$ for all values of $H$. More precisely, we are able to show that $n[\mathbb{E}(f(X_t)) - \mathbb{E}(f(X^n_t))]$ converges to a finite nonzero
limit which can be explicitly computed. This extends the result of [31] to $H > \frac{1}{2}$. Let us mention that the techniques of Malliavin calculus also allow us to provide an alternative and simpler proof of the fact that the rate of convergence of the numerical scheme (1.2) is of the order $n^{1-2H}$, and this rate is optimal, extending to the multidimensional case the results by Neuenkirch and Nourdin [18].

If the driven process is a standard Brownian motion, similar problems have been studied in [10, 13] and the references therein. See also [2] for the precise $L^2$-limit and also for a discussion on the “best” partition. In the case $\frac{1}{4} < H < \frac{1}{2}$ the SDE (1.1) can be solved using the theory of rough paths introduced by Lyons; see [15]. There are also a number of results on the rate of convergence of Euler-type numerical schemes in this case; see, for instance, the paper by Deya, Neuenkirch and Tindel [4] for a Milstein-type scheme without Lévy area in the case $\frac{1}{3} < H < \frac{1}{2}$, the paper by Friz and Riedel [5] for the $N$-step Euler scheme without involving iterated integrals and the monograph by Friz and Victoir [6].

The paper is organized as follows. The next section contains some basic materials on fractional calculus and Malliavin calculus that will be used throughout the paper, and introduces a matrix-valued Brownian motion and a generalized Rosenblatt process, both of which are key ingredients in our results on the asymptotic behavior of the error; see Section 6 and Section 8. In Section 3, we derive the necessary estimates for the uniform norms and Hölder seminorms of the processes $X$, $X^n$ and their Malliavin derivatives. In Section 4, we prove our result on the rate of convergence in $L^p$ for the numerical scheme (1.3). In Section 5, we prove a central limit theorem for weighted quadratic sums, and then in Section 6 we apply this result to the study of the asymptotic behavior of the error $\gamma_n(X_t - X^n_t)$ in case $H \in (\frac{1}{2}, \frac{3}{4})$. In Section 7, we study the $L^p$-convergence of some weighted random sums. In Section 8, we apply the results of Section 7 to establish the $L^p$-limit of $n(X_t - X^n_t)$ in case $H \in (\frac{3}{4}, 1)$. The weak approximation result is discussed in Section 9. In Section 10, we deal with the numerical scheme (1.2). In the Appendix, we prove some auxiliary results.

2. Preliminaries and notation. Throughout the paper we consider a fixed time interval $[0, T]$. To simplify the presentation we only deal with the uniform partition of this interval; that is, for each $n \geq 1$ and $i = 0, 1, \ldots, n$, we set $t_i = \frac{iT}{n}$. We use $C$ and $K$ to represent constants that are independent of $n$ and whose values may change from line to line.

2.1. Elements of fractional calculus. In this subsection we introduce the definitions of the fractional integral and derivative operators, and we review some properties of these operators.
Let \( a, b \in [0, T] \) with \( a < b \), and let \( \beta \in (0, 1) \). We denote by \( C^\beta(a, b) \) the space of \( \beta \)-Hölder continuous functions on the interval \([a, b]\). For a function \( x: [0, T] \to \mathbb{R} \), \( \|x\|_{a, b, \beta} \) denotes the \( \beta \)-Hölder seminorm of \( x \) on \([a, b]\), that is,

\[
\|x\|_{a, b, \beta} = \sup \left\{ \frac{|x_u - x_v|}{|v - u|^\beta}; a \leq u < v \leq b \right\}.
\]

We will also make use of the following seminorm:

\[
\|x\|_{a, b, \beta, n} = \sup \left\{ \frac{|x_u - x_v|}{|v - u|^\beta}; a \leq u < v \leq b, \eta(u) = u \right\}.
\]

Recall that for each \( n \geq 1 \) and \( i = 0, 1, \ldots, n \), \( t_i = \frac{iT}{n} \) and \( \eta(t) = t_i \) when \( t_i \leq t < t_i + \frac{T}{n} \).

We will denote the uniform norm of \( x \) on the interval \([a, b]\) as \( \|x\|_{a, b, \infty} \). When \( a = 0 \) and \( b = T \), we will simply write \( \|x\|_\infty \) for \( \|x\|_{0, T, \infty} \) and \( \|x\|_\beta \) for \( \|x\|_{0, T, \beta} \).

Let \( f \in L^1([a, b]) \) and \( \alpha > 0 \). The left-sided and right-sided fractional Riemann–Liouville integrals of \( f \) of order \( \alpha \) are defined, for almost all \( t \in (a, b) \), by

\[
I_{a+}^\alpha f(t) = \frac{1}{\Gamma(\alpha)} \int_a^t (t-s)^{\alpha-1} f(s) \, ds
\]

and

\[
I_{b-}^\alpha f(t) = \frac{(-1)^{-\alpha}}{\Gamma(\alpha)} \int_t^b (s-t)^{\alpha-1} f(s) \, ds,
\]

respectively, where \((-1)^{\alpha} = e^{-i\pi \alpha}\) and \(\Gamma(\alpha) = \int_0^\infty r^{\alpha-1} e^{-r} \, dr\) is the Gamma function. Let \( I_{a+}^\alpha(L^p) \) [resp., \( I_{a+}^\alpha(L^p) \)] be the image of \( L^p([a, b]) \) by the operator \( I_{a+}^\alpha \) [resp., \( I_{a+}^\alpha \)]. If \( f \in I_{a+}^\alpha(L^p) \) [resp., \( f \in I_{b-}^\alpha(L^p) \)] and \( 0 < \alpha < 1 \), then the fractional Weyl derivatives are defined as

\[
D_{a+}^\alpha f(t) = \frac{1}{\Gamma(1-\alpha)} \left( \frac{f(t)}{t-a} \right)^{\alpha} + \alpha \int_a^t \frac{f(t) - f(s)}{(t-s)^{\alpha+1}} \, ds
\]

and

\[
D_{b-}^\alpha f(t) = \frac{(-1)^\alpha}{\Gamma(1-\alpha)} \left( \frac{f(t)}{b-t} \right)^{\alpha} + \alpha \int_t^b \frac{f(t) - f(s)}{(s-t)^{\alpha+1}} \, ds,
\]

where \( a < t < b \).

Suppose that \( f \in C^\lambda(a, b) \) and \( g \in C^\mu(a, b) \) with \( \lambda + \mu > 1 \). Then, according to Young [33], the Riemann–Stieltjes integral \( \int_a^b f(t) \, dg \) exists. The following proposition can be regarded as a fractional integration by parts formula, and provides an explicit expression for the integral \( \int_a^b f(t) \, dg \) in terms of fractional derivatives. We refer to [34] for additional details.
Proposition 2.1. Suppose that \( f \in C^\lambda(a, b) \) and \( g \in C^\mu(a, b) \) with \( \lambda + \mu > 1 \). Let \( \lambda > \alpha \) and \( \mu > 1 - \alpha \). Then the Riemann–Stieltjes integral \( \int_a^b f \, dg \) exists, and it can be expressed as

\[
\int_a^b f \, dg = (-1)^\alpha \int_a^b D^{\alpha+1}_a f(t) D^{1-\alpha}_b g(t) \, dt,
\]

where \( g_b(t) = 1_{(a,b)}(t)(g(t) - g(b^-)) \).

The notion of Hölder continuity and the above result on the existence of Riemann–Stieltjes integrals can be generalized to functions taking values in some normed spaces. We fix a probability space \( (\Omega, \mathcal{F}, P) \) and denote by \( \| \cdot \|_p \) the norm in the space \( L^p := L^p(\Omega) \), where \( p \geq 1 \).

Definition 2.1. Let \( f = \{f(t), t \in [0,T]\} \) be a stochastic process such that \( f(t) \in L^p \) for all \( t \in [0,T] \). We say that \( f \) is Hölder continuous of order \( \beta > 0 \) in \( L^p \) if

\[
\|f(t) - f(s)\|_p \leq C|t - s|^\beta,
\]

for all \( s, t \in [0,T] \).

The following result shows that with proper Hölder continuity assumptions on \( f \) and \( g \), the Riemann–Stieltjes integral \( \int_0^T f \, dg \) exists, and equation (2.4) holds.

Proposition 2.2. Let the positive numbers \( p_0, \lambda, \mu, p, q \) satisfy \( p_0 \geq 1 \), \( \frac{1}{p} + \frac{1}{q} = 1 \) and \( \frac{1}{p_0} + \frac{1}{\mu} > \frac{1}{H} \). Assume that \( f = \{f(t), t \in [0,T]\} \) and \( g = \{g(t), t \in [0,T]\} \) are Hölder continuous stochastic processes of order \( \mu \) and \( \lambda \) in \( L^{p_0} \) and \( L^{p_0} \) respectively, and \( f(0) \in L^{p_0} \). Let \( \pi: 0 = t_0 < t_1 < \cdots < t_N = T \) be a partition on \( [0,T] \), and \( \xi_i : t_{i-1} \leq \xi_i \leq t_i \). Then the sum \( \sum_{i=1}^N f(\xi_i)[g(t_i) - g(t_{i-1})] \) converges in \( L^{p_0} \) to the Riemann–Stieltjes integral \( \int_0^T f \, dg \) as \( |\pi| \) tends to zero, where \( |\pi| = \max_{1 \leq i \leq N} |t_i - t_{i-1}| \), and equation (2.4) holds.

Proposition 2.2 can be proved through a slight modification of Zähle’s proof in the real-valued case [34] using Hölder’s inequality.

2.2. Elements of Malliavin calculus. We briefly recall some basic facts about the stochastic calculus of variations with respect to an fBm. We refer the reader to [22] for further details. Let \( B = \{B^1_t, \ldots, B^m_t\}, t \in [0,T] \) be an \( m \)-dimensional fBm with Hurst parameter \( H \in (\frac{1}{2}, 1) \), defined on some
The following estimate holds:

$$\mathbb{E}(B_i^j B_k^l) = \frac{1}{2} (t^{2H} + s^{2H} - |t - s|^{2H}) \delta_{ij}, \quad i, j = 1, \ldots, m,$$

for all \( s, t \in [0, T] \), where \( \delta_{ij} \) is the Kronecker symbol.

Let \( \mathcal{H} \) be the Hilbert space defined as the closure of the set of step functions \( \Omega \), complete probability space \((\Omega, \mathcal{F}, P)\). Namely, \( B \) is a mean zero Gaussian process with covariance

$$\mathbb{E}(B_i^j B_k^l) = \frac{1}{2} (t^{2H} + s^{2H} - |t - s|^{2H}) \delta_{ij}, \quad i, j = 1, \ldots, m,$$

Let \( \mathcal{H} \) be the Hilbert space defined as the closure of the set of step functions \( [0, T] \) with respect to the scalar product

$$\langle 1_{[0,s]}, 1_{[0,t]} \rangle_{\mathcal{H}} = \frac{1}{2} (t^{2H} + s^{2H} - |t - s|^{2H}).$$

It is easy to see that the covariance of fBm can be written as

$$\alpha_{\mathcal{H}} \int_0^t \int_0^s |u - v|^{2H - 2} du \, dv,$$

where \( \alpha_{\mathcal{H}} = H(2H - 1) \). This implies that

$$\langle \psi, \phi \rangle_{\mathcal{H}} = \alpha_{\mathcal{H}} \int_0^T \int_0^T \psi_u \phi_v |u - v|^{2H - 2} du \, dv$$

for any pair of step functions \( \phi \) and \( \psi \) on \( [0, T] \).

The elements of the Hilbert space \( \mathcal{H}, \) or more generally, of the space \( \mathcal{H}^{\otimes l} \) may not be functions, but distributions; see [28] and [29]. We can find a linear space of functions contained in \( \mathcal{H}^{\otimes l} \) in the following way: Let \( \mathcal{H}^{\otimes l} \)

be the linear space of measurable functions \( \phi \) on \( [0, T]^l \subset \mathbb{R}^l \) such that

$$\| \phi \|_{\mathcal{H}^{\otimes l}} := \alpha_{\mathcal{H}} \int_{[0,T]^l} |\phi_u| |\phi_v| |u_1 - v_1|^{2H - 2} \cdots |u_l - v_l|^{2H - 2} du \, dv < \infty,$$

where \( u = (u_1, \ldots, u_l), v = (v_1, \ldots, v_l) \in [0, T]^l \). Suppose \( \phi \in L^{1/H}([0, T]^l) \).

The following estimate holds:

$$\| \phi \|_{\mathcal{H}^{\otimes l}} \leq b_{H,l} \| \phi \|_{L^{1/H}([0, T]^l)} \quad \text{(2.6)}$$

for some constant \( b_{H,l} > 0 \); the case \( l = 1 \) was proved in [16], and the extension to general case is easy; see [9], equation (2.5).

The mapping \( \mathbf{1}_{[0,t_1]} \times \cdots \times \mathbf{1}_{[0,t_m]} \rightarrow (B_{i_1}^1, \ldots, B_{i_m}^m) \) can be extended to a linear isometry between \( \mathcal{H}^m \) and the Gaussian space spanned by \( B \). We denote this isometry by \( h \mapsto B(h) \). In this way, \( \{B(h), h \in \mathcal{H}^m\} \) is an isonormal Gaussian process indexed by the Hilbert space \( \mathcal{H}^m \).

Let \( S \) be the set of smooth and cylindrical random variables of the form

$$F = f(B_{s_1}, \ldots, B_{s_N}),$$

where \( N \geq 1 \) and \( f \in C^\infty_0(\mathbb{R}^{m \times N}) \). For each \( j = 1, \ldots, m \) and \( t \in [0, T] \), the derivative operator \( D^j F \) on \( F \in S \) is defined as the \( \mathcal{H} \)-valued random variable

$$D_t^j F = \sum_{i=1}^N \frac{\partial f}{\partial x^j_i}(B_{s_1}, \ldots, B_{s_N}) \mathbf{1}_{[0,s_i]}(t), \quad t \in [0, T].$$
We can iterate this procedure to define higher order derivatives $D^{j_1, \ldots, j_l} F$ which take values on $\mathcal{H}^\otimes l$. For any $p \geq 1$ and any integer $k \geq 1$, we define the Sobolev space $\mathbb{D}^{k,p}$ as the closure of $\mathcal{S}$ with respect to the norm

$$
\|F\|_{k,p}^p = \mathbb{E}[|F|^p] + \mathbb{E}\left[ \sum_{l=1}^k \left( \sum_{j_1, \ldots, j_l=1}^m \|D^{j_1, \ldots, j_l} F\|_{\mathcal{H}^\otimes l}^2 \right)^{p/2} \right].
$$

If $V$ is a Hilbert space, $\mathbb{D}^{k,p}(V)$ denotes the corresponding Sobolev space of $V$-valued random variables.

For any $j = 1, \ldots, m$, we denote by $\delta^j$ the adjoint of the derivative operator $D^j$. We say $u \in \text{Dom} \delta^j$ if there is a $\delta^j(u) \in L^2(\Omega)$ such that for any $F \in \mathbb{D}^{1,2}$ the following duality relationship holds:

$$
\mathbb{E}(\langle u, D^j F \rangle_{\mathcal{H}}) = \mathbb{E}(\delta^j(u) F).
$$

The random variable $\delta^j(u)$ is also called the Skorohod integral of $u$ with respect to the fBm $B^j$, and we use the notation $\delta^j(u) = \int_0^T u_t \delta B^j_t$.

Let $F \in \mathbb{D}^{1,2}$ and $u$ be in the domain of $\delta^j$ such that $Fu \in L^2(\Omega; \mathcal{H})$. Then (see [23]) $Fu$ belongs to the domain of $\delta^j$, and the following equality holds:

$$
\delta^j(Fu) = F\delta^j(u) - \langle D^j F, u \rangle_{\mathcal{H}},
$$

provided the right-hand side of (2.8) is square integrable.

Suppose that $u = \{u_t, t \in [0,T]\}$ is a stochastic process whose trajectories are Hölder continuous of order $\gamma > 1 - H$. Then, for any $j = 1, \ldots, m$, the Riemann–Stieltjes integral $\int_0^T u_t dB_t^j$ exists. On the other hand, if $u \in \mathbb{D}^{1,2}(\mathcal{H})$ and the derivative $D^j u \in \text{Dom} \delta^j$ exists and satisfies almost surely

$$
\int_0^T \int_0^T |D^j u_t||t-s|^{2H-2} ds dt < \infty,
$$

and $\mathbb{E}(\|D^j u\|_{L^1([0,T])}^2) < \infty$, then (see Proposition 5.2.3 in [23]) $\int_0^T u_t \delta B_t^j$ exists, and we have the following relationship between these two stochastic integrals:

$$
\int_0^T u_t dB_t^j = \int_0^T u_t \delta B_t^j + \alpha_H \int_0^T \int_0^T D^j u_t|t-s|^{2H-2} ds dt.
$$

The following result is Meyer’s inequality for the Skorohod integral; see, for example, Proposition 1.5.7 of [23]. Given $p > 1$ and an integer $k \geq 1$, there is a constant $c_{k,p}$ such that

$$
\|\delta^k(u)\|_p \leq c_{k,p} \|u\|_{\mathbb{D}^{k,p}(\mathcal{H}^\otimes k)} \quad \text{for all } u \in \mathbb{D}^{k,p}(\mathcal{H}^\otimes k).
$$
Applying (2.6) and then the Minkowski inequality to the right-hand side of (2.10) yields
\begin{equation}
\|\delta^k(u)\|_p \leq C \|u\|_{L^{1/H}([0,T]^p)}^p + C \sum_{l=1}^k \sum_{j_1,\ldots,j_l=1}^m \|D^{j_1,\ldots,j_l}u\|_{L^{1/H}([0,T]^p+l)}^p
\end{equation}
for all \(u \in \mathbb{D}^{k,p}(\mathcal{H}^\otimes k)\), provided \(pH \geq 1\).

2.3. Stable convergence. Let \(Y_n, n \in \mathbb{N}\) be a sequence of random variables defined on a probability space \((\Omega, \mathcal{F}, P)\) with values in a Polish space \((E, \mathcal{E})\). We say that \(Y_n\) converges stably to the limit \(Y\), where \(Y\) is defined on an extension of the original probability space \((\Omega', \mathcal{F}', P')\), if and only if for any bounded \(\mathcal{F}\)-measurable random variable \(Z\), it holds that \((Y_n, Z) \Rightarrow (Y, Z)\) as \(n \to \infty\), where \(\Rightarrow\) denotes the convergence in law.

Note that stable convergence is stronger than weak convergence but weaker than convergence in probability. We refer to [11] and [1] for more details on this concept.

2.4. A matrix-valued Brownian motion. The aim of this subsection is to define a matrix-valued Brownian motion that will play a fundamental role in our central limit theorem. First, we introduce two constants \(Q\) and \(R\) which depend on \(H\).

Denote by \(\mu\) the measure on \(\mathbb{R}^2\) with density \(|s-t|^{2H-2}\). Define, for each \(p \in \mathbb{Z}\),
\begin{equation}
Q(p) = T^{4H} \int_0^1 \int_p^{p+1} \int_0^t \int_p^s \mu(dv du) \mu(ds dt)
\end{equation}
and
\begin{equation}
R(p) = T^{4H} \int_0^1 \int_p^{p+1} \int_t^1 \int_p^s \mu(dv du) \mu(ds dt).
\end{equation}
It is not difficult to check that for \(\frac{1}{2} < H < \frac{3}{4}\), the series \(\sum_{p \in \mathbb{Z}} Q(p)\) and \(\sum_{p \in \mathbb{Z}} R(p)\) are convergent, and for \(H = \frac{3}{4}\), they diverge at the rate \(\log n\).

Then we set (we omit the explicit dependence of \(Q\) and \(R\) on \(H\) to simplify the notation)
\begin{equation}
Q = \sum_{p \in \mathbb{Z}} Q(p), \quad R = \sum_{p \in \mathbb{Z}} R(p),
\end{equation}
for the case $H \in (\frac{1}{2}, \frac{3}{4})$, and

\[ Q = \lim_{n \to \infty} \frac{\sum_{|p| \leq n} Q(p)}{\log n} = \frac{T^{4H}}{2}, \quad R = \lim_{n \to \infty} \frac{\sum_{|p| \leq n} R(p)}{\log n} = \frac{T^{4H}}{2}, \]

for the case $H = \frac{3}{4}$.

**Lemma 2.1.** The constants $Q$ and $R$ satisfy $R \leq Q$.

**Proof.** If $H = \frac{3}{4}$, we see from (2.12) that these two constants are both equal to $\frac{T^{4H}}{2}$. Suppose $H \in (\frac{1}{2}, \frac{3}{4})$. Consider the functions on $\mathbb{R}^2$ defined by $\varphi_p(v, s) = \mathbf{1}_{\{p \leq v \leq \Delta s \leq p + 1\}}$, $\psi_p(v, s) = \mathbf{1}_{\{p \leq \Delta s \leq v \leq p + 1\}}$, $p \in \mathbb{Z}$. Then

\[
\frac{1}{n} \left\| \sum_{p=0}^{n-1} (\varphi_p - \psi_p) \right\|_{L^2(\mathbb{R}^2, \mu)}^2 = \frac{2}{n} \sum_{p,q=0}^{n-1} \langle \mathbf{1}_{\{p \leq v \leq \Delta s \leq p + 1\}}, \mathbf{1}_{\{q \leq \Delta s \leq v \leq q + 1\}} \rangle_{L^2(\mathbb{R}^2, \mu)} - \langle \mathbf{1}_{\{p \leq v \leq \Delta s \leq p + 1\}}, \mathbf{1}_{\{q \leq \Delta s \leq v \leq q + 1\}} \rangle_{L^2(\mathbb{R}^2, \mu)}
\]

\[ = \frac{2}{n} \sum_{p,q=0}^{n-1} (Q(p - q) - R(p - q)). \]

It is easy to see that the above is equal to

\[ \frac{2}{n} \sum_{j=0}^{n-1} \sum_{k=-j}^{j} (Q(k) - R(k)). \]

It then follows from a Cesàro limit argument that the quantity in the right-hand side of the above converges to $2(Q - R)$ as $n$ tends to infinity. Therefore, $Q \geq R$. \( \square \)

Let $\tilde{W}^{0,ij} = \{ \tilde{W}^{0,ij}_t, t \in [0,T] \}$, $i \leq j$, $i, j = 1, \ldots, m$ and $\tilde{W}^{1,ij} = \{ \tilde{W}^{1,ij}_t, t \in [0,T] \}$, $i, j = 1, \ldots, m$ be independent standard Brownian motions. When $i > j$, we define $\tilde{W}^{0,ij} = \tilde{W}^{0,ji}$. The matrix-valued Brownian motion $(W^{ij})_{1 \leq i, j \leq m}$, $i, j = 1, \ldots, m$ is defined as follows:

\[ W^{ii} = \frac{\alpha H}{\sqrt{T}} (\sqrt{Q + R} \tilde{W}^{1,ii}) \]

and

\[ W^{ij} = \frac{\alpha H}{\sqrt{T}} (\sqrt{Q - R} \tilde{W}^{1,ij} + \sqrt{R} \tilde{W}^{0,ij}) \quad \text{when } i \neq j. \]
Notice that this definition makes sense because $R \leq Q$. The random matrix $W_t$ is not symmetric when $H < \frac{3}{4}$; see the plot and table below. For $i, j, i', j' = 1, \ldots, m$, the covariance $\mathbb{E}(W_t^{ij}W_s^{i'j'})$ is equal to

$$\frac{\alpha^2_H(t \wedge s)}{T}(R\delta_{j'i'}\delta_{ij} + Q\delta_{jj'}\delta_{ii'})$$

where $\delta$ is the Kronecker function.

In the Figure 1 and Table 1, we consider two quantities for $H \in (\frac{1}{2}, \frac{3}{4})$,

$$q = \frac{\alpha^2_H T}{3H}Q \quad \text{and} \quad r = \frac{\alpha^2_H T}{4H}R.$$ 

We see that the values of $q$ and $r$ approach 0.5 and 0 as $H$ tends to $\frac{1}{2}$, respectively, and both of them tend to infinity when $H$ gets closer to $\frac{3}{4}$.

2.5. A matrix-valued generalized Rosenblatt process. In this subsection we introduce a generalized Rosenblatt process which will appear in the limiting result proved in Section 8 when $H > \frac{3}{4}$. Consider an $m$-dimensional fBm $B_t = (B_t^1, \ldots, B_t^m)$ with Hurst parameter $H \in (\frac{3}{4}, 1)$. Define for $i_1, i_2 \in 1, \ldots, m$,

$$Z_{n,i_1,i_2}^j(t) := n \sum_{j=1}^{\lfloor nt/T \rfloor} \int_{t_j}^{t_{j+1}} (B_s^{i_1} - B_{t_j}^{i_1})\delta B_s^{i_2}.$$
When \( i_1 = i_2 = i \), we can write

\[
Z_{n,i}^i(t) = \frac{T^{2H}}{2n^{2H-1}} \sum_{j=1}^{[nt/T]} H_2(\xi_{n,i}^j),
\]

where \( H_2(x) = x^2 - 1 \) is the second degree Hermite polynomial and \( \xi_{n,i}^j = T^{-H}n^H(B^i_{t_{j+1}} - B^i_{t_j}) \). It is well known (see \([20]\)) that for each \( i = 1, \ldots, m \), the process \( Z_{n,i}^i(t) \) converges in \( L^2 \) to the Rosenblatt process \( R(t) \). We refer the reader to \([30]\) and \([32]\) for further details on the Rosenblatt process.

When \( i_1 \neq i_2 \), the stochastic integral \( \int_{t_j}^{t_{j+1}} (B^i_{s} - B^j_{s}) \delta B^s \) cannot be written as the second Hermite polynomial of a Gaussian random variable. Nevertheless, the process \( Z_{n,i_1,i_2}^i(t) \) is still convergent in \( L^2 \). Indeed, for any positive integers \( n \) and \( n' \), we have

\[
\mathbb{E}(Z_{n,i_1,i_2}^i(t)Z_{n',i_2}^i(t))
\]

\[
= nn' \sum_{k=0}^{[nt/T]} \sum_{k'=0}^{[nt'/T]} \mathbb{E} \left[ \int_{(k/n)T}^{(k+1)/nT} (B^i_{s} - B^i_{(k/n)T}) \delta B^i_{s} \right]
\]

\[
\times \int_{(k'/n')T}^{(k'+1)/n'T} (B^i_{s} - B^i_{(k'/n')T}) \delta B^i_{s} \right]
\]

\[
= nn' \alpha_H^2 \sum_{k=0}^{[nt/T]} \sum_{k'=0}^{[nt'/T]} \int_{(k/n)T}^{(k+1)/nT} \int_{(k'/n')T}^{(k'+1)/n'T} \mu(ds \, dt)
\]

\[
\rightarrow \frac{T^{2H}}{4} \int_0^t \int_0^t |u - v|^{4H-4} \, du \, dv
\]

\[
= c_H t^{4H-2},
\]

as \( n', n \to +\infty \), where \( c_H = \frac{T^{2H^2}(2H-1)}{4(4H-3)} \). This allows us to conclude that \( Z_{n,i_1,i_2}^i(t) \) is a Cauchy sequence in \( L^2 \). We denote by \( Z_{i}^{i_1,i_2} \) the \( L^2 \)-limit of \( Z_{n,i_1,i_2}^i(t) \). Then \( Z_{i}^{i_1,i_2} \) can be considered a generalized Rosenblatt process.
It is easy to show that
\[ \mathbb{E}(|Z_t^{i_1i_2} - Z_s^{i_1i_2}|^2) \leq C|t - s|^{4H - 2}, \]
and by the hypercontractivity property, we deduce
\[ (2.13) \quad \mathbb{E}||Z_t^{i_1i_2} - Z_s^{i_1i_2}|^p \leq C_p|t - s|^{p(2H - 1)} \]
for any \( p \geq 2 \) and \( s, t \in [0, T] \). By the Kolmogorov continuity criterion this implies that \( Z^{i_1i_2} \) has a Hölder continuous version of exponent \( \lambda \) for any \( \lambda < 2H - 1 \).

3. Estimates for solutions of some SDEs. The purpose of this section is to provide upper bounds for the Hölder seminorms of solutions of two types of SDEs. The first type [see (3.1)] covers equation (1.1) and its Malliavin derivatives, as well as all the other SDEs involving only continuous integrands which we will encounter in this paper. The second type [see (3.13)] deals with the case where the integrands are step processes. These SDEs arise from approximation schemes such as (1.2) and (1.3).

For any integers \( k, N, M \geq 1 \), we denote by \( \mathcal{C}_b^k(\mathbb{R}^M; \mathbb{R}^N) \) the space of \( k \) times continuously differentiable functions \( f: \mathbb{R}^M \rightarrow \mathbb{R}^N \) which are bounded together with their first \( k \) partial derivatives. If \( N = 1 \), we simply write \( \mathcal{C}_b^k(\mathbb{R}^M) \).

In order to simplify the notation we only consider the case when the fBm is one-dimensional, that is, \( m = 1 \). All results of this section can be generalized to the case \( m > 1 \). Throughout the remainder of the paper we let \( \beta \) be any number satisfying \( \frac{1}{2} < \beta < H \). The first two lemmas are path-wise results, and they will still hold when \( B \) is replaced by general Hölder continuous functions of index \( \gamma > \beta \). The constants appearing in the lemmas depend on \( \beta, H, T \) and the uniform and Hölder seminorms of the coefficients. We fix a time interval \( [\tau, T] \), and to simplify we omit the dependence on \( \tau \) and \( T \) of the uniform norm and \( \beta \)-Hölder seminorm on the interval \( [\tau, T] \).

**Lemma 3.1.** Fix \( \tau \in [0, T) \). Let \( V = \{V_t, t \in [\tau, T]\} \) be an \( \mathbb{R}^M \)-valued processes satisfying
\[ (3.1) \quad V_t = S_t + \int_\tau^t [g_1(V_u) + U^1_u V_u] \, du + \int_\tau^t [g_2(V_u) + U^2_u V_u] \, dB_u, \]
where \( g_1 \in \mathcal{C}_b(\mathbb{R}^M; \mathbb{R}^M), g_2 \in \mathcal{C}_b^1(\mathbb{R}^M; \mathbb{R}^M) \) and \( U^i = \{U^i_t, t \in [\tau, T]\}, i = 1, 2, \) and \( S = \{S_t, t \in [\tau, T]\} \) are \( \mathbb{R}^M \times \mathbb{R}^M \)-valued and \( \mathbb{R}^M \)-valued processes, respectively. We assume that \( S \) has \( \beta \)-Hölder continuous trajectories, and the processes \( U^i, i = 1, 2, \) are uniformly bounded by a constant \( C \).

(i) If \( U^1 = U^2 = 0 \), then we can find constants \( K \) and \( K' \) such that \( (t - s)^{\beta} \|B\|_\beta \leq K, \tau < s < t \leq T \) implies
\[ \|V\|_{s,t,\beta} \leq K'(\|B\|_\beta + 1) + 2\|S\|_\beta. \]
(ii) Suppose that there exist constants $K_0$ and $K'_0$ such that $(t-s)\beta \leq K_0$, $\tau \leq s < t \leq T$ implies
\begin{equation}
\|U^2\|_{s,t,\beta} \leq K'_0(\|B\|_\beta + 1).
\end{equation}
Then there exists a positive constant $K$ such that
\begin{equation}
\max\{|V|, \|V\|_{\beta}\} \leq Ke^{K\|B\|^{1/\beta}_\beta} (|S_T| + \|S\|_{\beta} + 1).
\end{equation}

**Proof.** The proof follows the approach used, for instance, by Hu and Nualart [8]. Let $\tau \leq s < t \leq T$. By the definition of $V$,
\begin{equation}
V_t - V_s = S_t - S_s + \int_s^t [g_1(V_u) + U_1^1 V_u] du + \int_s^t [g_2(V_u) + U_2^2 V_u] dB_u.
\end{equation}
Applying Lemma A.1(ii) to the vector valued function $f : (u, v) \rightarrow g_2(v) + uv$ and the integrator $z = B$, and taking $\beta' = \beta$ yields
\begin{equation}
|V_t - V_s| \leq \|S\|_{\beta}(t-s)^\beta + (\|g_1\|_\infty + C\|V\|_{s,t,\infty})(t-s)
+ K_1(\|g_2\|_\infty + C\|V\|_{s,t,\infty})\|B\|_{\beta}(t-s)^\beta
+ K_2(\|\nabla g_2\|_\infty + C\|V\|_{s,t,\beta})\|B\|_{\beta}(t-s)^{2\beta}
+ K_2\|V\|_{s,t,\infty}\|U^2\|_{s,t,\beta}\|B\|_{\beta}(t-s)^{2\beta}.
\end{equation}

Step 1. In the case $U^1 = U^2 = 0$ (which means that we can take $C = 0$ and $\|U^2\|_{s,t,\beta} = 0$), dividing both sides of (3.5) by $(t-s)^\beta$ and taking the H"older seminorm on the left-hand side, we obtain
\begin{equation}
\|V\|_{s,t,\beta} \leq \|S\|_{\beta} + c_1(t-s)^{1-\beta} + K_1 c_1 \|B\|_{\beta}
+ K_2 c_1 \|V\|_{s,t,\beta} \|B\|_{\beta}(t-s)^\beta,
\end{equation}
where (and throughout this section) we denote
\begin{equation}
c_1 = \max\{C, \|g_1\|_\infty, \|g_2\|_\infty, \|\nabla g_2\|_\infty\}.
\end{equation}
Take $K = \frac{1}{2}(K_2 c_1)^{-1}$. Then for any $\tau \leq s < t \leq T$ such that $(t-s)^\beta \|B\|_{\beta} \leq K$, we have
\begin{equation}
\|V\|_{s,t,\beta} \leq 2\|S\|_{\beta} + 2c_1(t-s)^{1-\beta} + 2K_1 c_1 \|B\|_{\beta},
\end{equation}
which implies (i).

Step 2. As in step 1, we divide (3.5) by $(t-s)^\beta$ and then take the H"older seminorm on the left-hand side to obtain
\begin{equation}
\|V\|_{s,t,\beta} \leq \|S\|_{\beta} + c_1(1 + \|V\|_{s,t,\infty})(t-s)^{1-\beta}
+ K_1 c_1(1 + \|V\|_{s,t,\infty})\|B\|_{\beta}
+ 2K_2 c_1 \|V\|_{s,t,\beta} \|B\|_{\beta}(t-s)^\beta
+ K_2 \|V\|_{s,t,\infty}\|U^2\|_{s,t,\beta}\|B\|_{\beta}(t-s)^\beta.
\end{equation}
If \((t-s)^\beta \|B\|_\beta \leq \frac{1}{2}(K_2c_1)^{-1}\), then the coefficient of \(\|V\|_{s,t,\beta}\) on the right-hand side of (3.8) is less or equal than \(\frac{1}{2}\). Thus we obtain
\[
\|V\|_{s,t,\beta} \leq 2\|S\|_\beta + 2c_1(1 + \|V\|_{s,t,\infty})(t-s)^{1-\beta} \\
+ 2K_1c_1(1 + \|V\|_{s,t,\infty})\|B\|_\beta \\
+ 2K_2\|V\|_{s,t,\infty}\|B\|_\beta (t-s)^\beta.
\]
On the other hand, assuming \((t-s)^\beta \|B\|_\beta \leq K_0\) and applying (3.2), we obtain
\[
\|V\|_{s,t,\beta} \leq 2\|S\|_\beta + C_1(1 + \|B\|_\beta)(1 + \|V\|_{s,t,\infty}),
\]
for some constant \(C_1\). This implies
\[
\|V\|_{s,t,\infty} \leq |V_s| + 2(t-s)^\beta \|S\|_\beta + C_1(t-s)^\beta(1 + \|B\|_\beta)(1 + \|V\|_{s,t,\infty}).
\]
Assuming \((t-s)^\beta \|B\|_\beta \leq \frac{1}{4c_1}\) and \((t-s)^\beta \leq \frac{1}{4c_1} \land \frac{1}{2}\), we obtain
\[
\|V\|_{s,t,\infty} \leq 2\|V_s\| + 2\|S\|_\beta + 1. \tag{3.10}
\]
Take \(\Delta = [\|B\|_\beta^{-1}\min(\frac{1}{4K_2c_1}, K_0, \frac{1}{4c_1})]^{1/\beta} \land (\frac{1}{4c_1} \land \frac{1}{2})^{1/\beta}\). We divide the interval \([\tau, T]\) into \(N = \left\lfloor \frac{T-\tau}{\Delta} \right\rfloor + 1\) subintervals and denote by \(s_1, s_2, \ldots, s_N\) the left endpoints of these intervals and \(s_{N+1} = T\). Applying inequality (3.10) to each interval \([s_i, s_{i+1}]\) for \(i = 1, \ldots, N\) yields
\[
\|V\|_{\infty} \leq 2^{N+1}(|S_\tau| + 2\|S\|_\beta + 1). \tag{3.11}
\]
From the definition of \(\Delta\) we get
\[
N \leq 1 + \frac{T}{\Delta} \leq 1 + T\max(C_2, C_3\|B\|_\beta^{1/\beta}), \tag{3.12}
\]
for some constants \(C_2\) and \(C_3\). From inequalities (3.11) and (3.12) we obtain the desired estimate for \(\|V\|_{\infty}\).

If \(t, s \in [\tau, T]\) satisfy \(0 \leq t - s \leq \Delta\), then from (3.9) and from the upper bound of \(\|V\|_{\infty}\) we can estimate \(\frac{V_t - V_s}{(t-s)^\beta}\) by the right-hand side of (3.3) for some constant \(K\). On the other hand, if \(t - s > \Delta\), then
\[
\frac{|V_t - V_s|}{(t-s)^\beta} \leq 2\|V\|_{\infty}\Delta^{-1}.
\]
We can obtain a similar estimate from the upper bound of \(\|V\|_{\infty}\) and from the definition of \(\Delta\). This gives then the desired estimate for \(\|V\|_\beta\), and hence we complete the proof of (ii). □

For the second lemma we fix \(n\) and consider the partition of \([0, T]\) given by \(t_i = i\frac{T}{n}, i = 0, 1, \ldots, n\). Define \(\eta(t) = t_i\) if \(t_i \leq t < t_i + \frac{\varepsilon}{n}\) and \(\varepsilon(t) = t_i + \frac{T}{n}\) if \(t_i \leq t \leq t_i + \frac{\varepsilon}{n}\).
LEMMA 3.2. Suppose that $S$, $g_i$, $U^i$, $i = 1, 2$ are the same as in Lemma 3.1. Let $g \in C([0, T])$. Let $V = \{V_t, t \in [\tau, T]\}$ be an $\mathbb{R}^M$-valued processes satisfying the equation

$$V_t = S_t + \int_{\varepsilon(\tau)}^{t \vee \varepsilon(\tau)} [g_1(V_{\eta(u)}) + U^1_{\eta(u)} V_{\eta(u)}] g(u - \eta(u)) du$$

(3.13)

$$+ \int_{\varepsilon(\tau)}^{t \vee \varepsilon(\tau)} [g_2(V_{\eta(u)}) + U^2_{\eta(u)} V_{\eta(u)}] dB_u.$$

(i) If $U^1 = U^2 = 0$, then we can find constants $K$ and $K'$ such that $(t - s)^\beta \|B\|_\beta \leq K$, $\tau \leq s \leq t \leq T$ implies

$$\|V\|_{s, t, \beta, n} \leq K' (\|B\|_\beta + 1) + 2\|S\|_\beta.$$

(ii) Suppose that there exist constants $K_0$ and $K'_0$ such that $(t - s)^\beta \|B\|_\beta \leq K_0$, $\tau \leq s < t \leq T$ implies

$$\|U^2\|_{s, t, \beta, n} \leq K'_0 (\|B\|_\beta + 1).$$

Then there exists a constant $K$ such that

$$\max\{\|V\|_\beta, \|V\|_{\beta}\} \leq Ke^{K\|B\|_\beta^{1/\beta} (|S_\tau| + \|S\|_\beta + 1)}.$$

REMARK 3.1. The proof of this result is similar to that of Lemma 3.1. Nevertheless, since the integral is discrete, we need to replace the Hölder seminorm $\| \cdot \|_{s, t, \beta}$ by the seminorm $\| \cdot \|_{s, t, \beta, n}$ introduced in (2.1).

PROOF OF LEMMA 3.2. Let $s, t \in [\tau, T]$ be such that $s < t$ and $s = \eta(s)$. This implies $s \geq \varepsilon(\tau)$. As in the proof of (3.5), applying Lemma A.1(i) [instead of Lemma A.1(ii)] yields

$$|V_t - V_s|$$

$$\leq \|S\|_\beta (t - s)^\beta + (\|g_1\|_\infty + C\|V\|_{s, t, \infty})\|g\|_\infty (t - s)$$

$$+ K_1 (\|g_2\|_\infty + C\|V\|_{s, t, \infty})\|B\|_\beta (t - s)^\beta$$

$$+ K_3 (\|\nabla g_2\|_\infty + C)\|V\|_{s, t, \beta, n} + \|V\|_{s, t, \infty}\|U^2\|_{s, t, \beta, n}) \|B\|_\beta (t - s)^2.$$

Dividing both sides of the above inequality by $(t - s)^\beta$ and taking the Hölder seminorm on the left-hand side, we obtain

$$\|V\|_{s, t, \beta, n} \leq \|S\|_\beta + (\|g_1\|_\infty + C\|V\|_{s, t, \infty})\|g\|_\infty (t - s)^{1-\beta}$$

(3.15)

$$+ K_1 (\|g_2\|_\infty + C\|V\|_{s, t, \infty})\|B\|_\beta$$

$$+ K_3 (\|\nabla g_2\|_\infty + C)\|V\|_{s, t, \beta, n} \|B\|_\beta (t - s)^\beta$$

$$+ K_3 \|V\|_{s, t, \infty}\|U^2\|_{s, t, \beta, n}) \|B\|_\beta (t - s)^2.$$. 
Step 1. In the case $U^1 = U^2 = 0$, (3.15) becomes

\[
\|V\|_{s,t,\beta,n} \\
\leq \|S\|_{\beta} + c_1 \|g\|_{\infty} (t-s)^{1-\beta} + K_1 c_1 \|B\|_{\beta} + K_3 c_1 \|V\|_{s,t,\beta,n} \|B\|_{\beta} (t-s)^{\beta},
\]

where $c_1$ is defined in (3.7). Taking $K = \frac{1}{2} (K_3 c_1)^{-1}$, for any $\tau \leq s < t \leq T$ such that $(t-s)^{\beta} \|B\|_{\beta} \leq K$, we have

\[
\|V\|_{s,t,\beta,n} \leq 2 \|S\|_{\beta} + 2 c_1 \|g\|_{\infty} (t-s)^{1-\beta} + 2 K_1 c_1 \|B\|_{\beta}.
\]

This completes the proof of (i).

Step 2. In the general case, we follow the proof of Lemma 3.1, except that we assume $s = \eta(s)$ and use the seminorm $\| \cdot \|_{s,t,\beta,n}$ instead of $\| \cdot \|_{s,t,\beta}$. We also apply (3.14) instead of (3.2). In this way we obtain inequality (3.9) with $\|V\|_{s,t,\beta}$ replaced by $\|V\|_{s,t,\beta,n}$, that is,

\[
(3.16) \quad \|V\|_{s,t,\beta,n} \leq 2 \|S\|_{\beta} + C_1 (1 + \|B\|_{\beta})(1 + \|V\|_{s,t,\infty})
\]

for some constant $C_1$. Inequality (3.10) remains the same,

\[
(3.17) \quad \|V\|_{s,t,\infty} \leq 2 \|V_s\| + 2 \|S\|_{\beta} + 1,
\]

provided $s = \eta(s)$, and both $t - s$ and $(t-s)^{\beta} \|B\|_{\beta}$ are bounded by some constant $C_4$.

Take $\Delta = (C_4^{1/\beta} \|B\|_{\beta}^{-1/\beta}) \wedge C_4$. We are going to consider two cases depending on the relation between $\Delta$ and $\frac{2T}{n}$.

If $\Delta > \frac{2T}{n}$, we take $N = \lceil \frac{2T - \varepsilon(\tau)}{\Delta} \rceil$ and divide the interval $[\varepsilon(\tau), \varepsilon(\tau) + N \frac{T}{n}]$ into $N$ subintervals of length $\Delta$. Since the length of each of these subintervals is larger than $\frac{T}{n}$, we are able to choose $N$ points $s_1, s_2, \ldots, s_N$ from each of these intervals such that $s_i = \varepsilon(\tau) + i \frac{T}{n}$, and $\eta(s_i) = s_i$, $i = 1, 2, \ldots, N$. On the other hand, we have $s_{i+1} = \frac{T}{n}$, $s_i \leq \Delta$ for all $i = 1, \ldots, N - 1$. Applying inequality (3.17) to each of the intervals $[s_1, s_2], [s_2, s_3], \ldots, [s_{N-1}, s_N], [s_N, T]$, yields

\[
(3.18) \quad \|V\|_{\varepsilon(\tau), T, \infty} \leq 2^{N+1} (|S_{\varepsilon(\tau)}| + 2 \|S\|_{\beta} + 1).
\]

From the definition of $\Delta$ we have

\[
(3.19) \quad N \leq \frac{2T}{\Delta} \leq K + K \|B\|_{\beta}^{1/\beta},
\]

for some constant $K$ depending on $T$ and $C_4$. From (3.18) and (3.19) and taking into account that

\[
(3.20) \quad \|V\|_{\tau, \varepsilon(\tau), \infty} = \|S\|_{\tau, \varepsilon(\tau), \infty} \leq |S_{\tau}| + T^\beta \|S\|_{\beta},
\]

we obtain the desired estimate for $\|V\|_{\infty}$.
If \( \Delta \leq \frac{2T}{n} \), that is, when \( n \leq \frac{2T}{\Delta} \leq K + K \|B\|^{1/\beta} \), then by equation (3.13) we have
\[
|V_t| \leq |V_{\eta(t)}| + |S_t - S_{\eta(t)}| + (c_1 + C|V_{\eta(t)}|)\|g\|_\infty(T/n)
+ (c_1 + C|V_{\eta(t)}|)\|B\|_\beta(T/n)^\beta
\leq A_n + B_n|V_{\eta(t)}|,
\]
for any \( t \in [\tau, T] \), where
\[
A_n = \|S\|_\beta(T/n)^\beta + c_1\|g\|_\infty(T/n) + c_1\|B\|_\beta(T/n)^\beta
\]
and
\[
B_n = 1 + C\|g\|_\infty(T/n) + C\|B\|_\beta(T/n)^\beta.
\]
Iterating this estimate, we obtain
\[
\|V\|_{\epsilon(\tau),T,\infty} \leq |S_{\epsilon(\tau)}|B_n^n + nA_nB_n^{n-1}
\leq K(|S_{\epsilon(\tau)}| + \|S\|_\beta + 1)e^{K\|B\|^{1/\beta}},
\]
for some constant \( K \) independent of \( n \), where we have used the inequality
\[
B_n \leq e^{K(1+\|B\|_\beta)n^{1-\beta}},
\]
and the fact that \( n \leq K + K\|B\|^{1/\beta} \) for some constant \( K \). Taking (3.20) into account, we obtain the desired upper bound for \( \|V\|_\infty \).

In order to show the upper bound for \( \|V\|_{\tau,T,\beta} \), we notice that if \( 0 \leq t - s \leq \Delta \), then from (3.16) and from the upper bound of \( \|V\|_{\tau,T,\infty} \), we have
\[
\|V\|_{\epsilon(s),t,\beta,n} \leq K(|S_{\tau}| + \|S\|_\beta + 1)e^{K\|B\|^{1/\beta}},
\]
for some constant \( K \). Thus
\[
\frac{|V_t - V_s|}{(t-s)^\beta} \leq \|V\|_{\epsilon(s),t,\beta,n} + \frac{|V_{\epsilon(s)} - V_s|}{(\epsilon(s) - s)^\beta}
\leq K(|S_{\tau}| + \|S\|_\beta + 1)e^{K\|B\|^{1/\beta}}.
\]
If \( t - s \geq \Delta \), we can obtain the upper bound of \( \|V\|_\beta \) by an argument similar to that in the proof of Lemma 3.1. The proof of (ii) is now complete. \( \Box \)

The following result gives upper bounds for the norm of Malliavin derivatives of the solutions of the two types of SDEs, (3.1) and (3.13). Given a process \( P = \{P_t, t \in [\tau, T]\} \) such that \( P_t \in \mathbb{D}^{N,2} \), for each \( t \) and some \( N \geq 1 \), we denote by \( \mathcal{D}_N^*P \) the maximum of the supnorms of the functions \( P_{r_0}, D_{r_1}P_{r_0}, \ldots, D_{r_N}^*P_{r_0} \) over \( r_0, \ldots, r_N \in [\tau, T] \), and denote by \( \mathcal{D}_N^{**}P \) the maximum of the random variable \( \mathcal{D}_N^*P \) and the supnorms of \( \|P\|_\beta \), \( \|D_{r_1}P\|_{\tau_1,T,\beta}, \ldots, \|D_{r_N}^*P\|_{\tau_N,T,\beta} \) over \( r_0, \ldots, r_N \in [\tau, T] \). If \( N = 0 \), we simply write \( \mathcal{D}_0^*P = \|P\|_\infty \) and \( \mathcal{D}_0^*P = \max(\|P\|_\infty, \|P\|_\beta) \).
Lemma 3.3. (i) Let $V$ be the solution of equation (3.1). Assume that $g_1 = g_2 = 0$. Suppose that $U^1$ are $U^2$ are uniformly bounded by a constant $C$, and assume that there exist constants $K_0$ and $K'_0$ such that $(t - s)^2\|B\|_\beta \leq K_0$, $\tau \leq s < t \leq T$ implies
\begin{equation}
\|U^2\|_{s,t,\beta} \leq K'_0(\|B\|_\beta + 1).
\end{equation}
Suppose that $S, U^1, U^2 \in \mathbb{D}^{N,2}$, where $N \geq 0$ is an integer, and $D_r S_t = D_r U^1_t = 0$, $i = 1, 2$, if $0 \leq t < r \leq T$, and suppose that there exists a constant $K > 0$ such that the random variables $\mathcal{G}_N S$, $\mathcal{P}_N U^1$, $\mathcal{P}_N U^2$ are less than or equal to $K e^{K \|B\|_\beta^{1/\beta}}$. Then there exists a constant $K' > 0$ such that $\mathcal{G}_N V$ is less than $K' e^{K'\|B\|_\beta^{1/\beta}}$.

(ii) Let $V$ be the solution of equation (3.13). Then the conclusion in (i) still holds true under the same assumptions, except that in (3.22) we replace $\|U^2\|_{s,t,\beta}$ by $\|U^2\|_{s,t,\beta,n}$.

Proof. We first show point (i). The upper bounds of $\|V\|_\infty$ and $\|V\|_\beta$ follow from Lemma 3.1(ii). The Malliavin derivative $D_r V_t$ satisfies the equation (see Proposition 7 in [26])
\begin{equation}
D_r V_t = S_t^{(1)} + \int_r^t U^1_u D_r V_u du + \int_r^t U^2_u D_r V_u dB_u
\end{equation}
while $t \in [r \vee \tau, T]$ and $D_r V_t = 0$ otherwise, where
\begin{equation}
S_t^{(1)} := D_r S_t + U^1_r V_r + \int_r^t [D_r U^1_u] V_u du + \int_r^t [D_r U^2_u] V_u dB_u
\end{equation}
for $t \in [r \vee \tau, T]$. Lemma 3.1(ii) applied to the time interval $[r, T]$, where $r \geq \tau$, implies that
\begin{equation*}
\max\{\|D_r V\|_{r,T,\infty}, \|D_r V\|_{r,T,\beta}\} \leq K e^{K\|B\|_\beta^{1/\beta}} (\|S_t^{(1)}\| + \|S_t^{(1)}\|_{r,T,\beta} + 1).
\end{equation*}
Therefore, to obtain the desired upper bound it suffices to show that there exists a constant $K$ independent of $r$ such that both $\|S_t^{(1)}\|_{r,T,\infty}$ and $\|S_t^{(1)}\|_{r,T,\beta}$ are less than or equal to $K e^{K\|B\|_\beta^{1/\beta}}$. Applying Lemma A.1(ii) to the second integral in (3.23) and noticing that $\|D_r U^2\|_\infty$, $\|D_r U^2\|_{r,T,\beta}$, $\|V\|_\infty$, $\|V\|_{r,T,\beta}$ are bounded by $K e^{K\|B\|_\beta^{1/\beta}}$, we see that the upper bound of $\|S_t^{(1)}\|_{r,T,\beta}$ is bounded by $K e^{K\|B\|_\beta^{1/\beta}}$. On the other hand, in order to show the upper bound for $\|S_t^{(1)}\|_{r,T,\beta}$, we calculate
\begin{equation*}
\frac{S_t^{(1)} - S_s^{(1)}}{(t-s)^\beta} \leq \|D_r S\|_{r,T,\beta} + (t-s)^{-\beta} \int_s^t [D_r U^1_u] V_u du
\end{equation*}
\begin{equation*}
+ (t-s)^{-\beta} \int_s^t [D_r U^2_u] V_u dB_u.
\end{equation*}
Now we can estimate each term of the above right-hand side as before. Taking the supremum over \( s, t \in [r, T] \) yields the upper bound of \( \|S^{(1)}\|_{r, T, \beta} \).

We turn to the second derivative. As before, we are able to find the equation of \( D^2_{r_1, r_2} V_t \); see Proposition 7 in [26]. The estimates of \( D^2_{r_1, r_2} V_t \) can then be obtained in the same way as above by applying Lemma 3.1(ii) and the estimates that we just obtained for \( V_t \) and \( D_s V_t \), as well as the assumptions on \( S \) and \( U^j \). The estimates of the higher order derivatives of \( V \) can be obtained analogously.

The proof of (ii) follows along the same lines, except that we use Lemma 3.2(ii) and Lemma A.1(i) instead of Lemma 3.1(ii) and Lemma A.1(ii).

\[ \square \]

**Remark 3.2.** Since \( \beta > \frac{1}{2} \), from Fernique’s theorem we know that \( K e^{K \|B\|_\beta^{1/\beta}} \) has finite moments of any order. So Lemma 3.3 implies that the uniform norms and Hölder seminorms of the solutions of (3.1) and (3.13) and their Malliavin derivatives have finite moments of any order. We will need this fact in many of our arguments.

The next proposition is an immediate consequence of Lemma 3.3. Recall that the random variables \( \mathcal{D}_N^*P \) and \( \mathcal{D}_NP \) are defined in Section 3.

**Proposition 3.1.** Let \( X \) be the solution of equation (1.1), and let \( X^n \) be the solution of the Euler scheme (1.2). Fix \( N \geq 0 \), and suppose that \( b \in C^N_b(\mathbb{R}^d, \mathbb{R}^d), \sigma \in C^{N+1}_b(\mathbb{R}^d, \mathbb{R}^d) \) (recall that we assume \( m = 1 \)). Then there exists a positive constant \( K \) such that the random variables \( \mathcal{D}_N X \) and \( \mathcal{D}_N X^n \) are bounded by \( K e^{K \|B\|_\beta^{1/\beta}} \) for all \( n \in \mathbb{N} \). If we further assume \( \sigma \in C^{N+2}_b(\mathbb{R}^d, \mathbb{R}^d) \), then the same upper bound holds for the modified Euler scheme (1.3).

**Proof.** We first consider the process \( X \), the solution to equation (1.1). The upper bounds for \( \|X\|_\infty \) and \( \|X\|_\beta \) follow from Lemma 3.1(ii). The Malliavin derivative \( D_r X_t \) satisfies the following linear stochastic differential equation:

\[
(3.24) \quad D_r X_t = \sigma(X_r) + \int_r^t \nabla b(X_u) D_r X_u \, du + \int_r^t \nabla \sigma(X_u) D_r X_u \, dB_u,
\]

while \( 0 < r \leq t \leq T \), and \( D_r X_t = 0 \) otherwise. Then it suffices to show that

\[
(3.25) \quad \sup_{r \in [0,T]} \mathcal{D}_M(D_r X) \leq K e^{K \|B\|_\beta^{1/\beta}},
\]

for \( M = N - 1 \). We can prove estimate (3.25) by induction on \( N \geq 1 \). Set \( S_t = \sigma(X_t), U^1_t = \nabla b(X_t) \) and \( U^2_t = \nabla \sigma(X_t) \). Applying Lemma 3.1(i) to \( X \)
we obtain that $U^2$ satisfies (3.22). Therefore, Lemma 3.3 implies that (3.25) holds for $M = 0$. Now we assume that
$$\sup_{r \in [0,T]} \mathcal{D}_M(D_r X) \leq Ke^{K\|B\|_\beta^{1/\beta}},$$
for some $0 \leq M \leq N - 2$. It is then easy to see that
$$\mathcal{D}^*_{M+1}(U^1) \vee \mathcal{D}^*_{M+1}(U^2) \vee \mathcal{D}_{M+1}(S) \leq Ke^{K\|B\|_\beta^{1/\beta}},$$
taking into account that $b \in C_b^N([R^d; R^d])$, $\sigma \in C_b^{N+1}([R^d; R^d \times m])$, which enables us to apply Lemma 3.3 to (3.24) to obtain the upper bound of the quantity
$$\sup_{r \in [0,T]} \mathcal{D}_{M+1}(D_r X).$$
The estimates of the Euler scheme and the modified Euler scheme and their derivatives can be obtained in the same way. We omit the proof, and we only point out that one more derivative of $\sigma$ is needed for the modified Euler scheme because the function $\nabla \sigma$ is involved in its equation. □

4. Rate of convergence for the modified Euler scheme and related processes. The main result of this section is the convergence rate of the scheme defined by (1.3) to the solution of the SDE (1.1). Recall that $\gamma_n$ is the function of $n$ defined in (1.5).

**Theorem 4.1.** Let $X$ and $X^n$ be solutions to equations (1.1) and (1.3), respectively. We assume $b \in C_b^3([R^d; R^d])$, $\sigma \in C_b^4([R^d; R^d \times m])$. Then for any $p \geq 1$ there exists a constant $C$ independent of $n$ (but dependent on $p$) such that
$$\sup_{0 \leq t \leq T} \mathbb{E}[|X^n_t - X_t|^p]^{1/p} \leq C \gamma_n^{-1}.$$

**Proof.** Denote $Y := X - X^n$. Notice that $Y$ depends on $n$, but for notational simplicity we shall omit the explicit dependence on $n$ for $Y$ and some other processes when there is no ambiguity. The idea of the proof is to decompose $Y$ into seven terms [see (4.7) below] and then study their convergence rate individually.

**Step 1.** By the definitions of the processes $X$ and $X^n$, we have
$$Y_t = \int_0^t [b(X_s) - b(X^n_s) + b(X^n_s) - b(X^n_{\eta(s)})] \, ds$$
$$+ \sum_{j=1}^m \int_0^t [\sigma^j(X_s) - \sigma^j(X^n_s) + \sigma^j(X^n_s) - \sigma^j(X^n_{\eta(s)})] \, dB^j_s$$
$$- H \sum_{j=1}^m \int_0^t (\nabla \sigma^j \sigma^j)(X^n_{\eta(s)})(s - \eta(s))^{2H-1} \, ds.$$
By denoting 
\[ \sigma^j_0(s) = (\nabla \sigma^j \sigma^j)(X^n_{\eta(s)}), \quad b_1(s) = \int_0^1 \nabla b(\theta X_s + (1 - \theta)X^n_s) \, d\theta, \]
\[ \sigma^j_1(s) = \int_0^1 \nabla \sigma^j(\theta X_s + (1 - \theta)X^n_s) \, d\theta, \]
we can write
\[ Y_t = \int_0^t b_1(s)Y_s \, ds + \sum_{j=1}^m \int_0^t \sigma^j_1(s)Y_s \, dB^j_s + \int_0^t [b(X^n_s) - b(X^n_{\eta(s)})] \, ds \]
\[ + \sum_{j=1}^m \int_0^t [\sigma^j(X^n_s) - \sigma^j(X^n_{\eta(s)})] \, dB^j_s - H \sum_{j=1}^m \int_0^t \sigma^j_0(s) (s - \eta(s))^{2H-1} \, ds. \]

Let \( \Lambda^n = \{ \Lambda^n_t, t \in [0,T] \} \) be the \( d \times d \) matrix-valued solution of the following linear SDE:
\[ \Lambda^n_t = I + \int_0^t b_1(s) \Lambda^n_s \, ds + \sum_{j=1}^m \int_0^t \sigma^j_1(s) \Lambda^n_s \, dB^j_s, \]
where \( I \) is the \( d \times d \) identity matrix. Applying the chain rule for the Young integral to \( \Gamma^n_t \Lambda^n_t \), where \( \Gamma^n_t, t \in [0,T] \) is the unique solution of the equation
\[ \Gamma^n_t = I - \int_0^t \Gamma^n_s b_1(s) \, ds - \sum_{j=1}^m \int_0^t \Gamma^n_s \sigma^j_1(s) \, dB^j_s, \]
for \( t \in [0,T] \), we see that \( \Gamma^n_t \Lambda^n_t = \Lambda^n_t \Gamma^n_t = I \) for all \( t \in [0,T] \). Therefore, \( \Lambda^n_t^{-1} \) exists and coincides with \( \Gamma^n_t \).

We can express the process \( Y_t \) in terms of \( \Lambda^n_t \) as follows:
\[ Y_t = \int_0^t \Lambda^n_t \Gamma^n_s [b(X^n_s) - b(X^n_{\eta(s)})] \, ds \]
\[ + \sum_{j=1}^m \int_0^t \Lambda^n_t \Gamma^n_s [\sigma^j(X^n_s) - \sigma^j(X^n_{\eta(s)})] \, dB^j_s \]
\[ - H \sum_{j=1}^m \int_0^t \Lambda^n_t \Gamma^n_s \sigma^j_0(s) (s - \eta(s))^{2H-1} \, ds. \]

The first two terms in the right-hand side of equation (4.3) can be further decomposed as follows:
\[ \int_0^t \Lambda^n_t \Gamma^n_s [\sigma^j(X^n_s) - \sigma^j(X^n_{\eta(s)})] \, dB^j_s \]
\[ Y = \int_0^t \Lambda^n_t \Gamma^n_s b^j_2(s - \eta(s)) dB^j_s \]

\[ + \sum_{i=1}^m \int_0^t \Lambda^n_t \Gamma^n_s \sigma^{j,i}_2(s)(B^i_s - B^i_{\eta(s)}) dB^j_s \]

\[ + \int_0^t \Lambda^n_t \Gamma^n_s \sigma^j_3(s)(s - \eta(s))^{2H} dB^j_s \]

\[ := I_{2,j}(t) + \sum_{i=1}^m I_{3,j,i}(t) + I_{4,j}(t), \]

where

\[ b^j_2(s) = \int_0^1 \nabla \sigma^j(\theta X^n_s + (1 - \theta)X^n_{\eta(s)})b(X^n_{\eta(s)}) d\theta, \]

\[ \sigma^{j,i}_2(s) = \int_0^1 \nabla \sigma^j(\theta X^n_s + (1 - \theta)X^n_{\eta(s)})\sigma^i(X^n_{\eta(s)}) d\theta, \]

\[ \sigma^j_3(s) = \frac{1}{2} \int_0^1 \nabla \sigma^j(\theta X^n_s + (1 - \theta)X^n_{\eta(s)}) \sum_{l=1}^m \sigma^l_0(s) d\theta \]

and

\[ \Lambda^n_t \int_0^t \Gamma^n_s [b(X^n_s) - b(X^n_{\eta(s)})] ds \]

\[ = \Lambda^n_t \int_0^t \Gamma^n_s b^3(s) \left[ b(X^n_{\eta(s)})(s - \eta(s)) + \sum_{j=1}^m \sigma^j(X^n_{\eta(s)})(B^j_s - B^j_{\eta(s)}) \right] \]

\[ + \frac{1}{2} \sum_{j=1}^m \sigma^j_0(s)(s - \eta(s))^{2H} \] ds

\[ := I_{11}(t) + \sum_{j=1}^m I_{12,j}(t) + I_{13}(t), \]

where \( b^3(s) = \int_0^1 \nabla b(\theta X^n_s + (1 - \theta)X^n_{\eta(s)}) d\theta \). We also denote

\[ I_{5,j}(t) = -H \Lambda^n_t \int_0^t \Gamma^n_s \sigma^j_0(s)(s - \eta(s))^{2H-1} ds. \]

Substituting equations (4.4), (4.5) and (4.6) into (4.3) yields

\[ Y = I_{11} + \sum_{j=1}^m I_{12,j} + I_{13} + \sum_{j=1}^m I_{2,j} + \sum_{j,i=1}^m I_{3,j,i} + \sum_{j=1}^m I_{4,j} + \sum_{j=1}^m I_{5,j}. \]
Step 2. Denote by \((\Lambda^n)_i, i = 1, \ldots, d\), the \(i\)th columns of \(\Lambda^n\). We claim that \((\Lambda^n)_i\) satisfy the conditions in Lemma 3.3 with \(M = d\), \(\tau = 0\), \(U^1_t = b_1(t)\), \(U^2_t = \sigma^1(t)\) and \(N = 2\). We first show that \(U^2\) satisfies (3.22). Taking into account that \(b \in C^3_b(\mathbb{R}^d; \mathbb{R}^d), \sigma \in C^4_b(\mathbb{R}^d; \mathbb{R}^{d \times m})\), it suffices to show that both \(X\) and \(X^n\) satisfy (3.22). This is clear for \(X\) because of Lemma 3.1(i). It follows from Lemma 3.2(i) that there exist constants \(K\) and \(K\) such that

\[
(t - s)^\beta \|B\|_\beta \leq K, \quad 0 \leq s < t \leq T \implies
\]

\[
\|X^n\|_{s,t,\beta,n} \leq K'(\|B\|_\beta + 1).
\]

Notice that

\[
\frac{|X^n_t - X^n_s|}{(t - s)^\beta} \leq \frac{|X^n_t - X^n_{\varepsilon(s)}|}{(t - \varepsilon(s))^\beta} + \frac{|X^n_{\varepsilon(s)} - X^n_s|}{(\varepsilon(s) - s)^\beta}
\]

\[
\leq \|X^n\|_{s,t,\beta,n} + \frac{|X^n_{\varepsilon(s)} - X^n_s|}{\varepsilon(s) - s}
\]

for \(t, s : t \geq \varepsilon(s)\), where we recall that \(\varepsilon(s) = t_{k+1}\) when \(s \in (t_k, t_{k+1})\). Therefore, to verify (3.22) for \(X^n\) it suffices to show that

\[
\|X^n\|_{s,t,\beta} \leq K'(\|B\|_\beta + 1)
\]

for \(s, t \in [t_k, t_{k+1})\) for some \(k\). But this follows immediately from (1.3). On the other hand, the fact that \(\mathcal{D}_2U^1\) and \(\mathcal{D}_2U^2\) are less than \(Ke^{K\|B\|_\beta^{1/\beta}}\) for some \(K\) follows from Proposition 3.1, and the assumption that \(b \in C^3_b(\mathbb{R}^d; \mathbb{R}^d), \sigma \in C^4_b(\mathbb{R}^d; \mathbb{R}^{d \times m})\), where \(\mathcal{D}_2^1\) and \(\mathcal{D}_2\) are defined in Section 3.

In the same way we can show that the columns of \(\Gamma^n\) satisfy the assumptions of Lemma 3.3. As a consequence, it follows from Lemma 3.3 that

\[
\mathcal{D}_2\Lambda^n \vee \mathcal{D}_2\Gamma^n \leq Ke^{K\|B\|_\beta^{1/\beta}}.
\]

Step 3. From (4.8) and from the fact that \(b \in C^3_b(\mathbb{R}^d; \mathbb{R}^d)\) and \(\sigma \in C^4_b(\mathbb{R}^d; \mathbb{R}^{d \times m})\), it follows that

\[
\mathbb{E}(|I_{11}(t)|^{p})^{1/p} \leq Cn^{-1} \quad \text{and} \quad \mathbb{E}(|I_{13}(t)|^{p})^{1/p} \leq Cn^{-2H}.
\]

Notice that \(n^{-1}\) and \(n^{-2H}\) are bounded by \(\gamma_n^{-1}\). Applying estimates (A.4) and (A.5), inequality (4.8) and Proposition 3.1, we have for any \(j\)

\[
\mathbb{E}(|I_{12,j}(t)|^{p})^{1/p} \leq Cn^{-1}, \quad \mathbb{E}(|I_{2,j}(t)|^{p})^{1/p} \leq Cn^{-1},
\]

\[
\mathbb{E}(|I_{4,j}(t)|^{p})^{1/p} \leq Cn^{-2H}.
\]

Now to complete the proof of the theorem it suffices to show that for any \(j\), \(\mathbb{E}((\sum_{i=1}^m I_{3,j,i}(t) + I_{5,j}(t)|^{p})^{1/p} \leq C\gamma_n^{-1}\). For any fixed \(j\) we make the decomposition

\[
\sum_{i=1}^m I_{3,j,i} + I_{5,j} = E_{1,j} + E_{2,j} + E_{3,j},
\]
where
\[ E_{1,j}(t) = \Lambda_t^n \sum_{i=1}^{m} \int_0^t [\Gamma^n_{s} \sigma^{i}_{2}(s) - \Gamma^n_{\eta(s)}(\nabla \sigma^{j}(s))(X^n_{\eta(s)})](B^i_s - B^i_{\eta(s)}) \, dB^j_s, \]
\[ E_{2,j}(t) = \Lambda_t^n \sum_{i=1}^{m} \int_0^t \Gamma^n_{\eta(s)}(\nabla \sigma^{j}(s))(X^n_{\eta(s)})(B^i_s - B^i_{\eta(s)}) \, dB^j_s \]
\[ - H \Lambda_t^n \int_0^t \Gamma^n_{\eta(s)}\sigma^{i}_{0}(s)(s - \eta(s))^{2H-1} \, ds, \]
\[ E_{3,j}(t) = H \Lambda_t^n \int_0^t (\Gamma^n_{\eta(s)} - \Gamma^n_{s})\sigma^{i}_{0}(s)(s - \eta(s))^{2H-1} \, ds. \]

Applying (4.8) for the quantities $\|\Lambda^n\|_{\infty}$ and $\|\Gamma^n\|_{\beta}$, it is easy to see that $\mathbb{E}(|E_{3,j}(t)|^p)^{1/p} \leq Cn^{1-2H-\beta}$ for any $\frac{1}{2} < \beta < H$. On the other hand, applying estimate (A.15) from Lemma A.5 to $E_{1,j}$, we obtain $\mathbb{E}(|E_{1,j}(t)|^p)^{1/p} \leq Cn^{1-3\beta}$ for any $\frac{1}{2} < \beta < H$. Notice that the exponents $n^{1-2H-\beta}$ and $n^{1-3\beta}$ are bounded by $\gamma_n^{-1}$ if $\beta$ is sufficiently close to $H$.

Taking into account the relationship between the Skorohod and path-wise integral, we can express the term $E_{2,j}$ as follows:

(4.12)
\[ E_{2,j}(t) = \Lambda_t^n \sum_{i=1}^{m} \sum_{k=0}^{\lfloor nt/T \rfloor} F_{t_k}^{n,i,j} \int_{t_k}^{t_{k+1} \wedge t} \int_{t_k}^{s} \delta B^i_u \delta B^j_s, \]

for $t \in [0,T]$, where $F_{t_k}^{n,i,j} = \Gamma^n_i(\nabla \sigma^{j}(s))(X^n_t)$, and we define $t_{n+1} = (n+1)T_n$. From (4.8) and Proposition 3.1, we have

(4.13) \[ \max\{|F_{t_k}^{n,i,j}|, |D_{r_1}F_{t_k}^{n,i,j}|, |D_{r_2}D_{r_1}F_{t_k}^{n,i,j}|\} \leq Ke^{K\|B\|_{1/\beta}^{1/\beta}}. \]

Hence, applying estimate (A.8) from Lemma A.4 to $E_{2,j}(t)$, we obtain $\mathbb{E}(|E_{2,j}(t)|^p)^{1/p} \leq C\gamma_n^{-1}$. The proof is now complete. \(\square\)

The following result provides a rate of convergence for the Malliavin derivatives of the modified scheme and some related processes. Recall that $\beta$ satisfies $\frac{1}{2} < \beta < H$.

**Lemma 4.1.** Let $X$ and $X^n$ be the processes defined by (1.1) and (1.3), respectively. Suppose that $\sigma \in C^\infty_b(\mathbb{R}^d; \mathbb{R}^{d \times m})$, $b \in C^\infty_b(\mathbb{R}^d; \mathbb{R}^d)$. Let $p \geq 1$. Then:

(i) There exists a constant $C$ such that the quantities $\|D_u X_t - D_u X^n_t\|_p$, $\|D_r D_s X_t - D_r D_s X^n_t\|_p$, $\|D_u D_r D_s X_t - D_u D_r D_s X^n_t\|_p$ are less than $Cn^{1-2\beta}$ for all $u, r, s, t \in [0, T]$ and $n \in \mathbb{N}$. 
(ii) Let \( V \) and \( V^n \) be \( d \)-dimensional processes satisfying the equations
\[
V_t = V_0 + \int_0^t f_1(X_u, X_u) V_u \, du + \sum_{j=1}^m \int_0^t f_2^j(X_u, X_u) V_u \, dB^j_u,
\]
\[
V^n_t = V_0 + \int_0^t f_1(X_u, X^n_u) V^n_u \, du + \sum_{j=1}^m \int_0^t f_2^j(X_u, X^n_u) V^n_u \, dB^j_u,
\]
where \( f_1 \in C_b^3(\mathbb{R}^d \times \mathbb{R}^d; \mathbb{R}^{d \times d}) \) and \( f_2^j \in C_b^4(\mathbb{R}^d \times \mathbb{R}^d; \mathbb{R}^{d \times d}) \). Then there exists a constant \( C \) such that the quantities \( \|V_t - V^n_t\|_p \), \( \|D_s V_t - D_s V^n_t\|_p \), \( \|D_r D_s V_t - D_r D_s V^n_t\|_p \) are less than \( Cn^{1-2\beta} \) for all \( r, s, t \in [0, T] \) and \( n \in \mathbb{N} \).

**Remark 4.1.** The above results still hold when the approximation process \( X^n \) is replaced by the one defined by the recursive scheme (1.2). The proof follows exactly along the same lines.

**Proof of Lemma 4.1.** (i) Taking the Malliavin derivative in both sides of (4.3), we obtain
\[
D_r(X_t - X^n_t) = \int_0^t D_r[\Lambda^n_T \Gamma^n_s(b(X^n_s) - b(X^n_{\eta(s)}))] \, ds
\]
\[
+ \sum_{j=1}^m \int_0^t D_r[\Lambda^n_r \Gamma^n_s(\sigma^j(X^n_s) - \sigma^j(X^n_{\eta(s)}))] \, dB^j_s
\]
\[
+ \sum_{j=1}^m \Lambda^n_r \Gamma^n_r(\sigma^j(X^n_r) - \sigma^j(X^n_{\eta(r)}))
\]
\[
- H \sum_{j=1}^m \int_0^t D_r[\Lambda^n_r \Gamma^n_s \rho^j(\eta(s))](s - \eta(s))^{2H-1} \, ds.
\]

Proposition 3.1 and equation (4.8) imply that the first, third and last terms of the above right-hand side have \( L^p \)-norms bounded by \( Cn^{1-2H} \). Applying estimate (A.16) from Lemma A.5 to the second term and noticing that \( \|X\|_\beta \) and \( \sup_{t \in [0, T]} \|D_r X\|_\beta \) have finite moments of any order, we see that its \( L^p \)-norm is also bounded by \( Cn^{1-2\beta} \).

Similarly, we can take the second derivative in (4.3) and then estimate each term individually as before to obtain that the upper bound of \( \|D_r D_s X_t - D_r D_s X^n_t\|_p \) is bounded by \( Cn^{1-2\beta} \).

(ii) Using the chain rule for Young’s integral we derive the following explicit expression for \( V_t - V^n_t \):
\[
V_t - V^n_t = \int_0^t \mathcal{T}_t Y^{-1}_s(f_1(X_s, X_s) - f_1(X^n_s, X^n_s)) \, V^n_s \, ds
\]
\[
(4.14) \quad + \sum_{j=1}^{m} \int_0^t \Upsilon_t \Upsilon_s^{-1} (f_j^2(X_s, X_s) - f_j^2(X_s, X_s^n)) V^n_s dB^j_s,
\]

where \( \Upsilon = \{ \Upsilon_t, t \in [0, T] \} \) is the \( \mathbb{R}^{d \times d} \)-valued process that satisfies
\[
\Upsilon_t = I + \int_0^t f_1(X_s, X_s) \Upsilon_t ds + \sum_{j=1}^{m} \int_0^t f_j^2(X_s, X_s) \Upsilon_t dB^j_s.
\]

Lemma 3.3 implies that there exists a constant \( K \) such that for all \( n \in \mathbb{N} \), \( u, r, s, t \in [0, T] \), we have
\[
(4.15) \quad \max \{ \Upsilon_t, D_s \Upsilon_t, D_r D_s \Upsilon_t, D_u D_r D_s \Upsilon_t \} \leq K e^{K \| B \|_p^{1/\beta}}.
\]

Therefore, applying estimate \((A.4)\) to the second integral in \((4.14)\) with \( \nu = 0 \) and taking into account the estimate of Lemma 4.1(i), we obtain
\[
\| V - V^n \|_p \leq C n^{1-2\beta}.
\]

Taking the Malliavin derivative on both sides of \((4.14)\), and then applying estimates \((A.4)\) from Lemmas A.3 and 4.1(i) as before, we can obtain the desired estimate for \( \| D_s V_t - D_s V^n_t \|_p \). The estimate for \( \| D_r D_s V_t - D_r D_s V^n_t \|_p \) can be obtained in a similar way. \( \square \)

We define \( \{ \Lambda_t, t \in [0, T] \} \) as the solution of the limiting equation of \((4.1)\), that is,
\[
(4.16) \quad \Lambda_t = I + \int_0^t \nabla b(X_s) \Lambda_s ds + \sum_{j=1}^{m} \int_0^t \nabla \sigma^j(X_s) \Lambda_s dB^j_s.
\]

The inverse of the matrix \( \Lambda_t \), denoted by \( \Gamma_t \), exists and satisfies
\[
\Gamma_t = I - \int_0^t \Gamma_t \nabla b(X_s) ds - \sum_{j=1}^{m} \int_0^t \Gamma_t \nabla \sigma^j(X_s) dB^j_s.
\]

It follows from Lemma 4.1 that if we assume that \( \sigma \in C_b^5(\mathbb{R}^d; \mathbb{R}^{d \times m}) \) and \( b \in C_b^4(\mathbb{R}^d; \mathbb{R}^d) \), then the estimate in Lemma 4.1(ii) holds with the pair \((V, V^n)\) being replaced by \((\Gamma_t, \Gamma^n_t)\) or \((\Lambda_t, \Lambda^n_t)\), \( i = 1, \ldots, d \), where the subindex \( i \) denotes the \( i \)-th column of each matrix.

5. Central limit theorem for weighted sums. Our goal in this section is to prove a central limit result for weighted sums (see Proposition 5.5 below) that will play a fundamental role in the proof of Theorem 6.1 in the next section. This result has an independent interest and we devote this entire section to it.
We recall that $B = \{B_t, t \in [0,T]\}$ is an $m$-dimensional fBm, and we assume that the Hurst parameter satisfies $H \in \left(\frac{1}{2}, \frac{3}{4}\right)$. For any $n \geq 1$ we set $t_j = \frac{jT}{n}$, $j = 0, \ldots, n$. Recall that $\eta(s) = t_k$ if $t_k \leq s < t_{k+1}$. Consider the $d \times d$ matrix-valued process

$$
\Xi_n^{i,j} = \gamma_n \sum_{k=0}^{\lfloor nt \rfloor} \int_{t_k}^{t_{k+1}} (B^i_s - B^i_{\eta(s)}) \delta B^j_s, \quad 1 \leq i, j \leq m,
$$

where we denote $\{t\} = \lfloor nt \rfloor$ for $t \in [0,T)$ and $\{T\} = t_{n-1}$.

**Proposition 5.1.** The following stable convergence holds as $n$ tends to infinity

$$(\Xi^n, B) \Rightarrow (W, B),$$

where $W = \{W_t, t \in [0,T]\}$ is the matrix-valued Brownian motion, introduced in Section 2.4, and $W$ and $B$ are independent.

**Proof.** From inequality (A.8) in Lemma A.4 it follows that

$$
\mathbb{E}(|\Xi^n_{t_k} - \Xi^n_{t_j}|^4) \leq C \left(\frac{k-j}{n}\right)^2,
$$

for any $j \leq k$. This implies the tightness of $(\Xi^n, B)$.

Then it remains to show the convergence of the finite dimensional distributions of $(\Xi^n, B)$ to that of $(W, B)$. To do this, we fix a finite set of points $r_1, \ldots, r_{L+1} \in [0,T]$ such that $0 = r_1 < r_2 < \cdots < r_{L+1} \leq T$ and define the random vectors $B_L = (B_{r_1} - B_{r_1}, \ldots, B_{r_{L+1}} - B_{r_{L+1}})$, $\Xi^n_L = (\Xi^n_{r_1}, \ldots, \Xi^n_{r_{L+1}} - \Xi^n_{r_{L+1}})$ and $W_L = (W_{r_2} - W_{r_1}, \ldots, W_{r_{L+1}} - W_{r_{L+1}})$. We claim that as $n$ tends to infinity, the following convergence in law holds:

$$(\Xi^n_L, B_L) \Rightarrow (W_L, B_L).$$

For notational simplicity, we add one term to each component of $\Xi^n_L$, and we define

$$
\Theta^n_l(i,j) := \Xi^n_{r_{l+1}} - \Xi^n_{r_l} + \zeta^{i,j}_{\{r_l\},n} = \gamma_n \sum_{k \in \{r_l\}} \zeta^{i,j}_{k,n},
$$

for $1 \leq l \leq L$, $1 \leq i, j \leq d$, where

$$
\zeta^{i,j}_{k,n} = \int_{t_k}^{t_{k+1}} (B^i_s - B^i_{t_k}) \delta B^j_s.
$$

Then Slutsky’s lemma implies that the convergence in law in (5.2) is equivalent to

$$(\Theta^n_l(i,j), 1 \leq i, j \leq d, 1 \leq l \leq L, B_L) \Rightarrow (W_L, B_L).$$
According to Peccati and Tudor [27] (see also Theorem 6.2.3 in [21]), to show the convergence in law of \((\Theta_n^L, B_L^L)\), it suffices to show the convergence of each component of \((\Theta_n^L, B_L^L)\) to the correspondent component of \((W_L, B_L)\) and the convergence of the covariance matrix.

The convergence of the covariance matrix of \(\Theta_n^L\) follows from Propositions 5.2 and 5.3 below. The convergence in law of each component to a Gaussian distribution follows from Proposition 5.4 below and the fourth moment theorem; see [24] and also Theorem 5.2.7 in [21]. This completes the proof. □

In order to show the convergence of the covariance matrix and the fourth moment of \(\Theta_n^L\) we first introduce the following notation:

\[
D_k = \{(s, t, v, u) : t_k \leq v \leq s \leq t_{k+1}, u, t \in [0, T]\},
\]

(5.4)

\[
D_{k_1, k_2} = \{(s, t, v, u) : t_{k_2} \leq v \leq s \leq t_{k_2+1}, t_{k_1} \leq u \leq t \leq t_{k_1+1}\}.
\]

The next two propositions provide the convergence of the covariance \(\mathbb{E}[\Theta_n^L(i', j')\Theta_n^L(i, j)]\) in the cases \(l = l'\) and \(l \neq l'\), respectively. We denote \(\beta_{k/n}(s) = 1_{[t_k, t_{k+1}]}(s)\).

**Proposition 5.2.** Let \(\Theta_l^p(i, j)\) be defined in (5.3). Then

\[
\mathbb{E}[\Theta_l^p(i', j')\Theta_l^p(i, j)] \to \alpha_H^2 \gamma_n \{r_{l+1}\} \int_{D_k} D_u^i D_t^j \Theta_l^p(i', j') \mu(du) \mu(ds dt),
\]

(5.5)

as \(n \to +\infty\). Here \(\delta_{ii'}\) is the Kronecker function, \(\alpha_H = H(2H - 1)\) and \(Q\) and \(R\) are the constants defined in (2.12).

**Proof.** The proof will involve several steps.

**Step 1.** Applying twice the integration by parts formula (2.7), we have

\[
\mathbb{E}[\Theta_l^p(i', j')\Theta_l^p(i, j)] = \alpha_H^2 \gamma_n \{r_{l+1}\} \int_{D_k} D_u^i D_t^j \Theta_l^p(i', j') \mu(du) \mu(ds dt),
\]

(5.6)

where we recall that \(\{t\} = \lfloor nt \rfloor T\) for \(t \in [0, T]\) and \(\{T\} = t_{n-1}\), and \(D_k\) is defined in (5.4). Since

\[
D_u^i D_t^j \Theta_l^p(i', j') = \gamma_n \{r_{l+1}\} \int_{D_k} D_u^i D_t^j \Theta_l^p(i', j') \mu(du) \mu(ds dt),
\]

(5.7)

\[
\mathbb{E}[\Theta_l^p(i', j')\Theta_l^p(i, j)] = \gamma_n \{r_{l+1}\} \int_{D_k} D_u^i D_t^j \Theta_l^p(i', j') \mu(du) \mu(ds dt),
\]
EULER SCHEMES OF SDE DRIVEN BY FBM

31

the left-hand side of (5.5) equals

\[ \alpha^2_H \gamma^2_n \sum_{k,k' \in \{r\}} \int \{1_{[t', \bar{t}]}(u) \beta_{k'/n}(t) \delta_{j'j} \delta_{ii'} \]

\[ + 1_{[t, t']}(u) \beta_{k/n}(u) \delta_{j'i'} \} \mu (dv \, du) \mu (ds \, dt) \]

\[ := \alpha^2_H \gamma^2_n (G_1 \delta_{jj'} \delta_{ii'} + G_2 \delta_{ji'} \delta_{ij}). \]

In the next two steps, we compute the limits of \( \gamma^2_n G_1 \) and \( \gamma^2_n G_2 \) as \( n \) tends to infinity in the case \( H \in (\frac{1}{2}, \frac{3}{4}) \) and in the case \( H = \frac{3}{4} \) separately.

Step 2. In this step, we consider the case \( H \in (\frac{1}{2}, \frac{3}{4}) \). Recall that

\[ Q(p) = T^{4H} \int_0^1 \int_{t_p}^{t_{p+1}} \int_0^s \mu (dv \, du) \mu (ds \, dt) \]

\[ = n^{4H} \int_{D_{k', k'} + p} \mu (dv \, du) \mu (ds \, dt), \]

which is independent of \( n \), where the set \( D_{k_1, k_2} \) is defined in (5.4). We can express \( \gamma^2_n G_1 \) in terms of \( Q(p) \) as follows:

\[ \gamma^2_n G_1 = n^{4H-1} \sum_{k,k' \in \{r\}} \int_{D_{k', k}} \mu (dv \, du) \mu (ds \, dt) \]

\[ = \frac{1}{n} \sum_{p \in \{r\} - \{r_{l+1}\}} \sum_{k'=(\{r\} - \{r_{l+1}\}) \cup \{r\}} Q(p) \]

\[ = \sum_{p=-\infty}^{\infty} \Psi^R_{l}(p) Q(p), \]

where

\[ \Psi^R_{l}(p) = (\frac{(\{r_{l+1}\} - p) \wedge \{r_{l+1}\} - (\{r\} - p) \vee \{r\}}{n})_1^{\{r\} - \{r_{l+1}\} \cup \{r_{l+1}\} - \{r\}}(p). \]

The term \( \Psi^R_{l}(p) \) is uniformly bounded and converges to \( \frac{r_{l+1} - r_l}{T} \) as \( n \) tends to infinity for any fixed \( p \). Therefore, taking into account that \( \sum_{p=-\infty}^{\infty} Q(p) = Q < \infty \), the dominated convergence theorem implies

\[ \lim_{n \to \infty} \gamma^2_n G_1 = \frac{r_{l+1} - r_l}{T} Q. \]

Similarly, we can show that

\[ \lim_{n \to \infty} \gamma^2_n G_2 = \frac{r_{l+1} - r_l}{T} R. \]
Step 3. In the case $H = \frac{3}{4}$, we can write

$$
\gamma_n^2 G_1 = \frac{n^2}{\log n} \sum_{k,k' = \{r_l\}} \int_{D_{k,k'}} \mu(du) \mu(ds) d \mu
$$

$$
= \frac{1}{n \log n} \sum_{p = \{r_l\} - \{r_{l+1}\}} \sum_{k' = \{r_l\}} Q(p)
$$

$$
- \frac{1}{n \log n} \left\{ \sum_{p = \{r_{l+1}\} - \{r_l\}} \sum_{k' = \{r_l\}} + \sum_{p = 1} \sum_{k' = \{r_{l+1}\} - p + 1} \right\} Q(p)
$$

$$
:= G_{11} + G_{12}.
$$

Taking into account that $Q(p)$ behaves like $1/|p|$ as $|p|$ tends to infinity, it is then easy to see that $G_{12}$ converges to zero. On the other hand, recall that $Q = \lim_{n \to \infty} \sum_{|p| < \infty} Q(p)$. This implies that $G_{11}$ converges to $Q(r_{l+1} - r_l)$. This gives the limit of $\gamma_n^2 G_1$. The limit of $\gamma_n^2 G_2$ can be obtained similarly.

Proposition 5.3. Let $l,l' \in \{1, \ldots, L\}$ be such that $l \neq l'$. Let $\Theta^n$ be defined as in (5.3). Then

$$
\lim_{n \to \infty} \mathbb{E}[\Theta^n_{l'}(l') \Theta^n_l(i,j)] = 0.
$$

Proof. Without any loss of generality, we assume $l' < l$. As in (5.6) we have

$$
\mathbb{E}[\Theta^n_{l'}(l') \Theta^n_l(i,j)] = \alpha_H^2 \gamma_n \sum_{k = \{r_l\}} \int_{D_k} D_t^i \Theta^n_{l'}(l') \mu(du) \mu(ds) dt.
$$

Taking into account (5.7), we can write

$$
\mathbb{E}[\Theta^n_{l'}(l') \Theta^n_l(i,j)]
$$

$$
= \alpha_H^2 \gamma_n^2 \sum_{k = \{r_l\}} \sum_{k' = \{r_{l+1}\}} \int_{D_k} \{1_{[t_{k'}, \delta]}(u) \beta_{k'/n}(t) \delta_{jj'} \delta_{ii'}
$$

$$
+ 1_{[t_{k'}, \omega]}(t) \beta_{k'/n}(u) \delta_{j'i'} \delta_{jj'}) \mu(du) \mu(ds) dt)
$$

$$
:= \alpha_H^2 \gamma_n^2 (G_1 \delta_{jj'} \delta_{ii'} + G_2 \delta_{j'i'} \delta_{jj'}).\]
In the case $H \in \left(\frac{1}{2}, \frac{3}{4}\right)$ we have

$$\gamma_n^2 \tilde{G}_1 = n^{4H-1} \sum_{k=\{r_l\}}^{\{r_{l+1}\}} \sum_{k'=\{r_{l'}\}}^{\{r_{l'+1}\}} \int_{D_k} 1_{[\tilde{t}, \tilde{t}]}(u) \beta_{k'/n}(t) \mu(du) \mu(ds dt)$$

$$= \frac{1}{n} \sum_{p=\{r_l\} - \{r_{l+1}\}}^{\{r_{l'+1}\} - \{r_{l'}\}} \sum_{k'=\{r_{l'}\} \cap \{r_{l+1}\}}^{\{r_{l' + 1}\} - p} Q(p)$$

$$= \sum_{p=0}^{\infty} \Phi_n^l(p) Q(p),$$

where $\Phi_n^l(p)$ is equal to

$$\max\left\{\left(\{r_{l+1}\} - p\right) \land \{r_{l+1}\} - \{r_l\} \lor \{r_{l+1}\}, 0\right\} 1_{\{\{r_l\} - \{r_{l+1}\}, \{r_{l+1}\} - \{r_l\}\}}(p).$$

The term $\Phi_n^l(p)$ is uniformly bounded and converges to 0 as $n$ tends to infinity for any fixed $p$ because $l < l'$. Therefore, taking into account that $\sum_{p=0}^{\infty} Q(p) = Q < \infty$, the dominated convergence theorem implies that $\gamma_n^2 \tilde{G}_1$ converges to zero as $n$ tends to infinity. Similarly, we can show that $\gamma_n^2 \tilde{G}_2$ converges to zero as $n$ tends to infinity.

In the case $H = \frac{3}{4}$, since

$$\gamma_n^2 \tilde{G}_1 = \frac{n^2}{\ln n} \sum_{k=\{r_l\}}^{\{r_{l+1}\}} \sum_{k'=\{r_{l'}\}}^{\{r_{l'+1}\}} \int_{D_k} \mu(du) \mu(ds dt)$$

$$= \frac{1}{\ln n} \sum_{p=\{r_l\} - \{r_{l+1}\}}^{\{r_{l'+1}\} - \{r_{l'}\}} \sum_{k'=\{r_{l'}\} \cap \{r_{l+1}\}}^{\{r_{l' + 1}\} - p} Q(p),$$

we have

$$\gamma_n^2 \tilde{G}_1 \leq \frac{1}{\ln n} \sum_{p=\{r_l\} - \{r_{l+1}\}}^{\{r_{l'+1}\} - \{r_{l'}\}} \sum_{k'=\{r_{l'}\} \cap \{r_{l+1}\}}^{\{r_{l' + 1}\} - p} Q(p)$$

$$\leq \frac{1}{\ln n} \sum_{p=0}^{\infty} (p + 1) Q(p).$$

Noticing that $Q(p) = O(\frac{1}{|p|^2})$, we conclude that $\gamma_n^2 \tilde{G}_1 \leq \frac{C}{\ln n}$. This shows that $\gamma_n^2 \tilde{G}_1$ converges to zero as $n$ tends to infinity. In the same way we can show that $\gamma_n^2 \tilde{G}_2$ converges to zero. □
The following estimate is needed in the calculation of the fourth moment of \( \Theta_n^I(i, j) \) in Proposition 5.4.

**Lemma 5.1.** Let \( H \in (\frac{1}{2}, \frac{3}{4}] \). We have the following estimate:

\[
\sum_{k_1, k_2, k_3, k_4 = 0}^{n-1} \langle \beta_{k_1/n}, \beta_{k_2/n} \rangle H \langle \beta_{k_3/n}, \beta_{k_4/n} \rangle H \langle \beta_{k_5/n}, \beta_{k_4/n} \rangle H \langle \beta_{k_1/n}, \beta_{k_4/n} \rangle H \\
\leq C n^{-2} \gamma_n^{-2}.
\]

**Proof.** Since the indices \( k_1, k_2, k_3, k_4 \) are symmetric, it suffices to consider the case \( k_1 \leq k_2 \leq k_3 \leq k_4 \). By definition of the inner product we have

\[
\sum_{0 \leq k_1 \leq k_2 \leq k_3 \leq k_4 \leq n-1} \langle \beta_{k_1/n}, \beta_{k_2/n} \rangle H \langle \beta_{k_3/n}, \beta_{k_4/n} \rangle H \langle \beta_{k_5/n}, \beta_{k_4/n} \rangle H \langle \beta_{k_1/n}, \beta_{k_4/n} \rangle H \\
= \frac{T^{4 H}}{2 n^{8 H}} \sum_{k_1=0}^{n-1} \sum_{k_2=k_1}^{n-1} \sum_{k_3=k_2}^{n-1} \sum_{k_4=k_3}^{n-1} (|k_2 - k_1 + 1|^{2H} + |k_2 - k_1 - 1|^{2H} \\
- 2|k_2 - k_1|^{2H}) \\
\times ((|k_3 - k_2 + 1|^{2H} + |k_3 - k_2 - 1|^{2H} \\
- 2|k_3 - k_2|^{2H}) \\
\times ((|k_4 - k_3 + 1|^{2H} + |k_4 - k_3 - 1|^{2H} \\
- 2|k_4 - k_3|^{2H}) \\
\times ((|k_4 - k_1 + 1|^{2H} + |k_4 - k_1 - 1|^{2H} \\
- 2|k_4 - k_1|^{2H}).
\]

Denote \( p_i = k_{i+1} - k_i, i = 1, 2, 3 \). Then the above sum is bounded by

\[
C n^{1-8H} \sum_{p_1, p_2, p_3 = 1}^{n-1} p_1^{2H-2} p_2^{2H-2} p_3^{2H-2} (p_1 + p_2 + p_3)^{2H-2},
\]

which is again bounded by

\[
C n^{1-8H} \sum_{p_1, p_2, p_3 = 1}^{n-1} p_1^{2H-2} p_2^{2H-2} p_3^{4H-4}.
\]

In the case \( H \in (\frac{1}{2}, \frac{3}{4}) \), the series \( \sum_{p_3=1}^{n-1} p_3^{4H-4} \) is convergent. When \( H = \frac{3}{4} \), it is bounded by \( C \log n \). So the above sum is bounded by \( C n^{-4H-1} \) if \( \frac{1}{2} < H < \frac{3}{4} \) and bounded by \( C n^{-4} \log n \) if \( H = \frac{3}{4} \). The proof is complete. \( \square \)

The following proposition contains a result on the convergence of the fourth moment of \( \Theta_n^I(i, j) \).
PROPOSITION 5.4. The fourth moment of $\Theta_n^p(i, j)$ and $3\mathbb{E}(|\Theta_n^p(i, j)|^2)^2$ converge to the same limit as $n \to \infty$.

PROOF. Applying the integration by parts formula (2.7) yields

$$\mathbb{E}[\Theta_n^p(i, j)^4]$$

$$\begin{align*}
&= \alpha_H^2 \gamma_n \sum_{k=\{r_1\}}^{\{r_{i+1}\}} \int_{D_k} \mathbb{E}[D_u^i D_t^j [\Theta_n^p(i, j)^2]] \mu(dv du) \mu(ds dt) \\
&= \alpha_H^2 \gamma_n \sum_{k=\{r_1\}}^{\{r_{i+1}\}} \int_{D_k} \mathbb{E}[\{3\Theta_n^p(i, j)^2 J_u^i J_t^j [\Theta_n^p(i, j)] + 6\Theta_n^p(i, j) J_u^i J_t^j [\Theta_n^p(i, j)] \times J_u^i J_t^j [\Theta_n^p(i, j)]] \mu(dv du) \mu(ds dt) \\
&:= \overline{G}_1 + \overline{G}_2.
\end{align*}$$

Since $D_u^i J_t^j [\Theta_n^p(i, j)]$ is deterministic, it is easy to see that $\overline{G}_1 = 3\mathbb{E}(|\Theta_n^p(i, j)|^2)^2$. We have shown the convergence of $\mathbb{E}(|\Theta_n^p(i, j)|^2)$ in Proposition 5.2. It remains to show that $\overline{G}_2 \to 0$ as $n \to \infty$.

Applying again the integration by parts formula (2.7) yields

$$\overline{G}_2 = 6\alpha_H^4 \gamma_n^2 \sum_{k,k' = \{r_1\}}^{\{r_{i+1}\}} \int_{D_k \times D_{k'}} D_u^i J_t^j \{ J_u^i J_t^j [\Theta_n^p(i, j)] J_u^i J_t^j [\Theta_n^p(i, j)] \} \times \mu(dv' du') \mu(ds' dt') \mu(dv du) \mu(ds dt).$$

Using equation (5.7) we can derive the inequalities

$$\overline{G}_2 \leq 6\alpha_H^4 \gamma_n^4 \sum_{k,k',h,h' = \{r_1\}}^{\{r_{i+1}\}} \int_{D_k \times D_{k'}} \{ (h/n(t)h/n(t')h/n(u)h/n(u')) + \beta_{h/n}(t)\beta_{h/n}(u')\beta_{h/n}(u)\beta_{h/n}(t') \} \times \mu(dv' du') \mu(ds' dt') \mu(dv du) \mu(ds dt)$$

$$\leq 12\alpha_H^4 \gamma_n^4 \sum_{k,k',h,h' = \{r_1\}}^{\{r_{i+1}\}} (h/n, h/n, h) (h'/n, h/n, h) (h/n, h'/n, h) \times (h'/n, h/n, h).$$

The convergence of $\overline{G}_2$ to zero now follows from Lemma 5.1. □
We can now establish a central limit theorem for weighted sums based on the previous proposition. Recall that 
\[ \zeta_{k,n}^{i,j} = \int_{t_k}^{t_{k+1}} (B^i_s - B^i_{t_k}) \delta B^j_s, \quad k = 0, \ldots, n - 1 \] and \( \zeta_{n,n}^{i,j} = 0. \)

**Proposition 5.5.** Let \( f = \{f_t, t \in [0,T]\} \) be a stochastic process with values on the space of \( d \times d \) matrices and with Hölder continuous trajectories of index greater than \( \frac{1}{2} \). Set, for \( i, j = 1, \ldots, m, \)
\[
\Psi_{i,j}^n(t) = \sum_{k=0}^{\{t\}} f_{t_k}^{i,j} \zeta_{k,n}^{i,j}.
\]
Then, the following stable convergence in the space \( D([0,T]) \) holds as \( n \) tends to infinity:
\[
\{\gamma_n \Psi_n(t), t \in [0,T]\} \rightarrow \left\{ \left( \int_0^t f_s^{i,j} dW_s^{i,j} \right)_{1 \leq i,j \leq m}, t \in [0,T] \right\},
\]
where \( W \) is a matrix-valued Brownian motion independent of \( B \) with the covariance introduced in Section 2.4.

**Proof.** This proposition is an immediate consequence of the central limit result for weighted random sums proved in [3]. In fact, the process \( \Psi_{i,j}^n(t) \) satisfies the required conditions due to Proposition 5.1 and the estimate (5.1). \( \square \)

6. **CLT for the modified Euler scheme in the case \( H \in \left( \frac{1}{2}, \frac{3}{4} \right] \).** The following central limit type result shows that in the case \( H \in \left( \frac{1}{2}, \frac{3}{4} \right] \), the process \( \gamma_n(X - X^n) \) converges stably to the solution of a linear stochastic differential equation driven by a matrix-valued Brownian motion independent of \( B \) as \( n \) tends to infinity.

**Theorem 6.1.** Let \( H \in \left( \frac{1}{2}, \frac{3}{4} \right] \), and let \( X, X^n \) be the solutions of the SDE (1.1) and recursive scheme (1.3), respectively. Let \( W = \{W_t, t \in [0,T]\} \) be the matrix-valued Brownian motion introduced in Section 2.4. Assume \( \sigma \in C^5_b(\mathbb{R}^d; \mathbb{R}^{d \times m}) \) and \( b \in C^4_b(\mathbb{R}^d; \mathbb{R}^d) \). Then the following stable convergence in the space \( C([0,T]) \) holds as \( n \) tends to infinity:

\[
\{\gamma_n(X_t - X^n_t), t \in [0,T]\} \rightarrow \{U_t, t \in [0,T]\},
\]
where \( \{U_t, t \in [0,T]\} \) is the solution of the linear \( d \)-dimensional SDE
\[
U_t = \int_0^t \nabla b(X_s) U_s \, ds + \sum_{j=1}^m \int_0^t \nabla \sigma^j(X_s) U_s \, dB^j_s
\]
\[
+ \sum_{i,j=1}^m \int_0^t (\nabla \sigma^j \sigma^i)(X_s) \, dW_s^{i,j}.
\]
Remark 6.1. It follows from [13] that when $B$ is replaced by a standard Brownian motion, the process $\sqrt{n}(X - X^n)$ converges in law to the unique solution of the $d$-dimensional SDE
\begin{equation}
    dU_t = \nabla b(X_t)U_t dt + \sum_{j=1}^m \nabla \sigma^j(X_t) U_t dB_t^j
    \tag{6.3}
    \quad + \sqrt{\frac{T}{2}} \sum_{j,i=1}^m (\nabla \sigma^j \sigma^i)(X_t) dW_t^{ij}
\end{equation}
with $U_0 = 0$. Here $W^{ij}, i, j = 1, \ldots, m$ are independent one-dimensional Brownian motions, independent of $B$. To compare our Theorem 6.1 with this result, we let the Hurst parameter $H$ converge to $\frac{1}{2}$. Then the constant $R$ will converge to 0, and $\frac{\alpha H}{\sqrt{T}}(\sqrt{Q - \alpha H})$ converges to $\sqrt{\frac{T}{2}}$. This formally recovers equation (6.3).

Remark 6.2. The process $U$ defined in (6.2) is given by
\begin{equation}
    U_t = \sum_{i,j=1}^m \int_0^t \Lambda_t \Gamma_s(\nabla \sigma^j \sigma^i)(X_s) dW_s^{ij}, \quad t \in [0, T],
    \tag{6.4}
\end{equation}
where we recall that $\Lambda$ is defined in (4.16) and $\Gamma$ is its inverse.

Proof of Theorem 6.1. Recall that $Y_t = X_t - X^n_t$. We would like to show that the process $\{\gamma_n Y_t, B_t, t \in [0, T]\}$ converges weakly in $C([0, T]; \mathbb{R}^{d+m})$ to $\{U_t, B_t, t \in [0, T]\}$. To do this, it suffices to prove the following:

(i) convergence of the finite dimensional distributions of $\{\gamma_n Y_t, B_t, t \in [0, T]\}$;
(ii) tightness of the process $\{\gamma_n Y_t, B_t, t \in [0, T]\}$.

We first show (i). Recall the decomposition of $Y_t$ given in (4.7) and (4.11), and recall the estimates obtained for each term in the decomposition of $Y_t$. Since the other terms converge to zero in $L^p$ for $p \geq 1$, from the Slutsky theorem it suffices to consider the convergence of the finite dimensional distributions of $\{\gamma_n \sum_{j=1}^m E_{2,j}(t), B_t, t \in [0, T]\}$, where $E_{2,j}$ is defined in Theorem 4.1 step 3. Set
\begin{equation}
    F^{i,j}_s := \Lambda_t \Gamma_s(\nabla \sigma^j \sigma^i)(X^n_s) - \Lambda_t \Gamma_s(\nabla \sigma^j \sigma^i)(X_s).
    \tag{6.5}
\end{equation}
It follows from Lemma 4.1 and Remark 4.1 that
\[
    \sup_{r,s,t \in [0, T]} \left( ||F^{i,j}_t||_p \vee ||D_s F^{i,j}_t||_p \vee ||D_r D_s F^{i,j}_t||_p \right) \leq C n^{1-2\beta}.
\]
Denote
\( \tilde{E}_{2,j}(t) = \Lambda_t \sum_{i=1}^{m} \sum_{k=0}^{\lfloor nt/T \rfloor} \Gamma_{tk} (\nabla \sigma^j \sigma^i)(X_{tk}) \int_{tk}^{tk+1} \int_{tk}^{s} \delta B^i_u \delta B^j_s, \)
for \( t \in [0, T), \) and \( \tilde{E}_{2,j}(T) = \tilde{E}_{2,j}(T^-). \) Then applying Lemma A.4 (A.9) with \( F^{i,j} \) defined by (6.5), we obtain that
\( \gamma_n \| E_{2,j}(t) - \tilde{E}_{2,j}(t) \|_p \leq C \gamma_n n^{-H_n^{1-2\beta}}, \)
which converges to zero as \( n \to \infty \) since \( \beta \) can be taken as close as possible to \( H. \) By Slutsky’s theorem again, it suffices to consider the convergence of the finite dimensional distributions of
\( \left\{ \gamma_n \sum_{j=1}^{m} \tilde{E}_{2,j}(t), B_t, t \in [0, T] \right\}. \)

Applying Proposition 5.5 to the family of processes \( f^{i,j}_t = \Gamma_t (\nabla \sigma^j \sigma^i)(X_t), \)
we obtain the convergence of the finite dimensional distributions of
\( \left\{ \gamma_n \sum_{j=1}^{m} \Gamma_t \tilde{E}_{2,j}(t), B_t, t \in [0, T] \right\} \)
to those of \( \left\{ \Gamma_t U_t, B_t, t \in [0, T] \right\}. \) This implies the convergence of the finite dimensional distributions of
\( \left\{ \gamma_n \sum_{j=1}^{m} \tilde{E}_{2,j}(t), B_t, t \in [0, T] \right\} \)
to those of \( \left\{ U_t, B_t, t \in [0, T] \right\}. \)

To show (ii), we prove the following tightness condition:
\( \sup_{n \geq 1} \mathbb{E}( \gamma_n (X_t - X^n_t) - \gamma_n (X_s - X^n_s)^4) \leq C(t-s)^2. \)
Taking into account (4.7) and (4.11), we only need to show the above inequality for \( \gamma_n I_{11}, \gamma_n I_{12,j}, \gamma_n I_{13}, \gamma_n I_{2,j}, \gamma_n I_{4,j}, \gamma_n E_{1,j}, \gamma_n E_{2,j} \) and \( \gamma_n E_{3,j} \). The tightness for the terms \( \gamma_n I_{11}, \gamma_n I_{13} \) and \( \gamma_n E_{3,j} \) is clear. Now we consider the tightness of the term \( I_{2,j}. \) We write
\( I_{2,j}(t) - I_{2,j}(s) = (\Lambda^n_t - \Lambda^n_s) \int_{s}^{t} \Gamma^n_{s \alpha} b^j_2(s)(s - \eta(s)) dB^j_s + \int_{s}^{t} \Lambda^n_{s \alpha} \Gamma^n u b^j_2(u)(u - \eta(u)) dB^j_u. \)
Then it follows from Lemma A.3 (A.4) that
\[
\mathbb{E}(|\gamma_n (\Lambda^n_1 - \Lambda^n_2) \int_0^t \Gamma^n b_j^2 (s) (s - \eta(s)) dB^j_s|^4) \leq C (t - s)^{4\beta} (\mathbb{E} \| \Lambda^n \|^8) ^{1/2} \\
\leq C (t - s)^{4\beta}.
\]

Lemma A.3 (A.4) also implies that the fourth moment of the second term is bounded by \(C (t - s)^{4H}\). The tightness for \(\gamma_n I_{12,j}, \gamma_n I_{4,j}, \gamma_n E_{1,j}, \gamma_n E_{2,j}\) can be obtained in a similar way by applying the estimates (A.5) and (A.4) from Lemma A.3, (A.15) from Lemma A.5, and (A.8) from Lemma A.4, respectively. \(\Box\)

7. **A limit theorem in \(L^p\) for weighted sums.** Following the methodology used in [3], we can show the following limit result for random weighted sums. The proof uses the techniques of fractional calculus and the classical decompositions in large and small blocks.

Consider a double sequence of random variables \(\zeta = \{\zeta_{k,n}, n \in \mathbb{N}, k = 0, 1, \ldots, n\}\), and for each \(t \in [0, T]\), we denote
\[
\gamma_n(t) := \sum_{k=0}^{\lfloor nt/T \rfloor} \zeta_{k,n}.
\]

**Proposition 7.1.** Fix \(\lambda > 1 - \beta\), where \(0 < \beta < 1\). Let \(p \geq 1\) and \(p', q' > 1\) such that \(\frac{1}{p} + \frac{1}{q} = 1\) and \(pp' > \frac{1}{q}, \ pq' > \frac{1}{q}\). Let \(g_n\) be the sequence of processes defined in (7.1). Suppose that the following conditions hold true:

(i) for each \(t \in [0, T]\), \(g_n(t) \to z(t)\) in \(L^{pq'}\);
(ii) for any \(j, k = 0, 1, \ldots, n\) we have
\[
\mathbb{E}(|g_n(kT/n) - g_n(jT/n)|^{pq'}) \leq C(|k - j|/n)^{\lambda pq'}.
\]

Let \(f = \{f(t), t \in [0, T]\}\) be a process such that \(\mathbb{E}(\|f\|_{\beta}^{pp'}) \leq C\) and \(\mathbb{E}(|f(0)|^{pp'}) \leq C\). Then for each \(t \in [0, T]\),
\[
F^n(t) := \sum_{k=0}^{\lfloor nt/T \rfloor} f(t_k) \zeta_{k,n} \to \int_0^t f(s) dz(s) \quad \text{in } L^p \text{ as } n \to \infty.
\]

**Remark 7.1.** The integral \(\int_0^t f(s) dz(s)\) is interpreted as a Young integral in the sense of Proposition 2.2, which is well defined because \(f\) and \(z\), as functions on \([0, T]\) with values in \(L^{pq'}\) and \(L^{pq'}\), are Hölder continuous [conditions (i) and (ii) together imply the Hölder continuity of \(z\) of order \(\beta\) and \(\lambda\), respectively. Recall that the Hölder continuity of a function with values in \(L^p\) is defined in (2.5).]
Applying Proposition 7.2, convergence (7.4) still holds true if the condition \( \mathbb{E}(\|f\|_{p,p}^p) \leq C \) is weakened by assuming that \( f \) is Hölder continuous of order \( \beta \) in \( L^{pp'} \). The proof will be similar to that of Proposition 7.1.

**Proof of Proposition 7.1.** Given two natural numbers \( m < n \) we consider the associated partitions of the interval \([0,T]\) given by \( t_k = \frac{kT}{n}, \) \( k = 0,1,\ldots,n \) and \( u_l = \frac{lt}{m}, \) \( l = 0,1,\ldots,m \). Then we have the decomposition

\[
(7.3) \quad F^n(t) = \sum_{l=0}^{\lfloor mt/T \rfloor} f(u_l) \sum_{k \in I_m(l)} \zeta_{k,n} + \sum_{l=0}^{\lfloor mt/T \rfloor} \sum_{k \in I_m(l)} [f(t_k) - f(u_l)]\zeta_{k,n},
\]

where \( I_m(l) := \{k: 0 \leq k \leq \lfloor \frac{mT}{n} \rfloor, t_k \in [u_l, u_{l+1})\} \).

Because of condition (i) and the assumption that \( \mathbb{E}(\|f(t)\|_{p,p}^p) \leq C \) for all \( t \in [0,T] \), the first term on the right-hand side of the above expression converges in \( L^p \), as \( n \) tends to infinity, to

\[
\sum_{l=0}^{\lfloor mt/T \rfloor} f(u_l)[z(u_{l+1}) - z(u_l)].
\]

Applying Proposition 2.2 to \( f \) and \( z \) we obtain that the above Riemann–Stieltjes sum converges to the Young integral \( \int_0^t f(s) \, dz(s) \) in \( L^p \) as \( m \) tends to infinity. To show convergence (7.2) it suffices to show that

\[
(7.4) \quad \lim_{m \to \infty} \sup_{n \in \mathbb{N}} \mathbb{E} \left( \left\| \sum_{l=0}^{\lfloor mt/T \rfloor} \sum_{k \in I_m(l)} [f(t_k) - f(u_l)]\zeta_{k,n} \right\|^p \right) = 0.
\]

Notice that \( k \) belongs to \( I_m(l) \) if and only if \( u_l \leq t_k < \varepsilon(u_{l+1}) \) and \( t_k \leq \eta(t) \). Recall that \( \varepsilon(u) = t_{k+1} \) if \( t_k < u \leq t_{k+1} \) and \( \eta(u) = t_k \) if \( t_k \leq u < t_{k+1} \). As a consequence, we can write

\[
\sum_{l=0}^{\lfloor mt/T \rfloor} \sum_{k \in I_m(l)} [f(t_k) - f(u_l)]\zeta_{k,n} = \sum_{l=0}^{\lfloor mt/T \rfloor} \int_{(a_l,b_l)} [f(s) - f(a_l)] \, dg_n(s),
\]

where \( a_l = u_l \) and \( b_l = \varepsilon(u_{l+1}) \land (\eta(t) + \frac{T}{n}) \). By the fractional integration by parts formula,

\[
(7.5) \quad \int_{(a_l,b_l)} [f(s) - f(a_l)] \, dg_n(s) = (-1)^\alpha \int_{a_l}^{b_l} D_{a_l}^{\alpha}[f(s) - f(a_l)]D_{b_l}^{1-\alpha}[g_n(s) - g_n(b_l)] \, ds,
\]
where we take $\alpha \in (1 - \lambda, \beta)$. By (2.2), it is easy to show that

$$
|D_{a_l}^\alpha [f(s) - f(a_l)]| \leq \frac{1}{\Gamma(1 - \alpha)} \frac{\beta}{\beta - \alpha} \|f\|_\beta (s - a_l)^{\beta - \alpha}
$$

(7.6)

$$
\leq C\|f\|_\beta m^{\alpha - \beta}.
$$

On the other hand, by (2.3) we have

$$
|D_{b_l}^{1-\alpha} [g_n(s) - g_n(b_l -)]|
$$

(7.7)

$$
= \frac{1}{\Gamma(\alpha)} \left| \frac{g_n(s) - g_n(b_l -)}{(b_l - s)^{1-\alpha}} \right| + (1 - \alpha) \int_s^{b_l} \frac{g_n(s) - g_n(u)}{(u - s)^{2-\alpha}} du.
$$

We can calculate the integral in the above equation explicitly.

$$
\int_s^{b_l} \frac{g_n(s) - g_n(u)}{(u - s)^{2-\alpha}} du
$$

(7.8)

$$
= \sum_{k: t_k \in [\varepsilon(s), b_l]} [g_n(s) - g_n(t_k)] \int_{t_k}^{t_k+1} (u - s)^{\alpha - 2} du
$$

$$
= \sum_{k: t_k \in [\varepsilon(s), b_l]} [g_n(s) - g_n(t_k)] \frac{1}{1 - \alpha} [(t_k - s)^{\alpha - 1} - (t_k + 1 - s)^{\alpha - 1}].
$$

Substituting (7.6), (7.7) and (7.8) into (7.5), we obtain

$$
\left| \int_{(a_l, b_l)} [f(s) - f(a_l)] dg_n(s) \right|
$$

$$
\leq C\|f\|_\beta m^{\alpha - \beta} \int_{a_l}^{b_l} |D_{b_l}^{1-\alpha} [g_n(s) - g_n(b_l -)]| ds
$$

$$
\leq C\|f\|_\beta m^{\alpha - \beta} \sum_{k: t_k \in [\varepsilon(a_l), b_l]} \int_{t_k}^{t_{k+1}} |D_{b_l}^{1-\alpha} [g_n(s) - g_n(b_l -)]| ds
$$

$$
\leq C\|f\|_\beta m^{\alpha - \beta} \sum_{k: t_k \in [\varepsilon(a_l), b_l]} |g_n(t_k) - g_n(b_l -)| \int_{t_k}^{t_{k+1}} (b_l - s)^{\alpha - 1} ds
$$

$$
+ C\|f\|_\beta m^{\alpha - \beta} \sum_{k: t_k \in [\varepsilon(a_l), b_l]} |g_n(t_k) - g_n(t_j)|
$$

$$
\times \int_{t_k}^{t_{k+1}} [(t_j - s)^{\alpha - 1} - (t_{j+1} - s)^{\alpha - 1}] ds.
$$
We denote the first term in the right-hand side of the above expression by $A_{1,l}$ and the second one by $A_{2,l}$.

Applying the Minkowski inequality, we see that the quantity

$$E\left(\left|\sum_{l=0}^{[mt/T]} A_{1,l}\right|^p\right)^{1/p}$$

is less than

$$Cm^{\alpha-\beta} \left|\sum_{l=0}^{[mt/T]} \sum_{k: t_k \in [\eta(a_l), b_l)} E(\|f\|_p^n |g_n(t_k) - g_n(b_l-)|^p)^{1/p} \int_{t_k}^{t_{k+1}} (b_l-s)^{\alpha-1} ds\right|,$$

so by applying the H"older inequality, condition (ii) and the assumption $E(\|f\|_p^{pp}) \leq C$ to the above, we can show that quantity (7.9) is less than

$$Cm^{\alpha-\beta} \left|\sum_{l=0}^{[mt/T]} \sum_{k: t_k \in [\eta(a_l), b_l)} (b_l - t_k)^\lambda \int_{t_k}^{t_{k+1}} (b_l-s)^{\alpha-1} ds\right|.$$  

Since

$$\sum_{k: t_k \in [\eta(a_l), b_l)} (b_l - t_k)^\lambda \int_{t_k}^{t_{k+1}} (b_l-s)^{\alpha-1} ds$$

$$= \frac{1}{\alpha} \left(\frac{T}{n}\right)^{\lambda+\alpha} + \sum_{k: t_k \in [\eta(a_l), b_l-T/n)} (b_l - t_k)^\lambda \int_{t_k}^{t_{k+1}} (b_l-s)^{\alpha-1} ds$$

$$\leq \frac{1}{\alpha} \left(\frac{T}{n}\right)^{\lambda+\alpha} + \frac{T}{n} \sum_{k: t_k \in [\eta(a_l), b_l-T/n)} (b_l - t_k)^\lambda (b_l - t_{k+1})^{\alpha-1}$$

$$\leq \frac{1}{\alpha} \left(\frac{T}{n}\right)^{\lambda+\alpha} + C \frac{T n}{m^{-\alpha+1-\lambda}}$$

$$\leq C m^{-\alpha-\lambda},$$

where in the second inequality we used the assumption that $\alpha > 1-\lambda$ and the fact that the number of partition points $\{t_k, k=0,1,\ldots,n\}$ in $[\eta(a_l), b_l - \frac{T}{n})$ is bounded by $\frac{n}{m}$, the estimate (7.10) of (7.9) implies that

$$E\left(\left|\sum_{l=0}^{[mt/T]} A_{1,l}\right|^p\right)^{1/p} \leq Cm^{\alpha-\beta} \sum_{l=0}^{[mt/T]} m^{-\alpha-\lambda} \leq Cm^{1-\beta-\lambda} \to 0$$

as $m$ tends to $\infty$.  

Using an argument similar to the estimate of quantity (7.9), it can be shown that the quantity
\[
E \left( \left\| \sum_{l=0}^{\lfloor mt/T \rfloor} A_{2,l} \right\|^p \right)^{1/p}
\]
is less than
\[
C m^{\alpha - \beta} \sum_{l=0}^{\lfloor mt/T \rfloor} \sum_{k,j : \eta(a_l) \leq t_k < t_j < b_l} \left| t_k - t_j \right|^\lambda
\times \int_{t_k}^{t_{k+1}} \left| (t_j - s)^{\alpha - 1} - (t_{j+1} - s)^{\alpha - 1} \right| ds.
\]
The summand in the above can be estimated as follows:
\[
\sum_{k,j : \eta(a_l) \leq t_k < t_j < b_l} \left| t_k - t_j \right|^\lambda \int_{t_k}^{t_{k+1}} \left| (t_j - s)^{\alpha - 1} - (t_{j+1} - s)^{\alpha - 1} \right| ds
\leq C n \left( \frac{T}{n} \right)^{\alpha + \lambda}
+ \sum_{k,j : \eta(a_l) \leq t_{k+1} < t_j < b_l} \left| t_{k+1} - t_j \right|^\lambda \int_{t_k}^{t_{k+1}} \left| (t_j - s)^{\alpha - 1} - (t_{j+1} - s)^{\alpha - 1} \right| ds
\leq C n \left( \frac{T}{n} \right)^{\alpha + \lambda}
+ C n^{-2} \left( \frac{T}{n} \right)^{2-\lambda-\alpha} \sum_{k,j : \eta(a_l) \leq t_{k+1} < t_j < b_l} (j - k - 1)^{\alpha - 2 + \lambda}
\leq C n^{-2} \left( \frac{T}{n} \right)^{2-\alpha - \lambda} \sum_{k,j : \eta(a_l) \leq t_{k+1} < t_j < b_l} (j - k - 1)^{\alpha - 2 + \lambda}
\leq C n^{-2} \left( \frac{T}{n} \right)^{2-\alpha - \lambda} \sum_{p=2}^{n/m} (p - 1)^{\alpha - 2 + \lambda}
\leq C m^{-\alpha - \lambda}.
\]
Therefore, we have
\[
E \left( \left\| \sum_{l=0}^{\lfloor mt/T \rfloor} A_{2,l} \right\|^p \right)^{1/p} = C m^{\alpha - \beta} \left\| \sum_{l=0}^{\lfloor mt/T \rfloor} m^{-\alpha - \lambda} \right\| \to 0 \quad \text{as } m \to \infty.
\]
The above convergence and equality (7.11) together imply convergence (7.4). The proof is now complete. □

This result has the following two consequences.
Corollary 7.1. Let \( B = \{ B_t, t \in [0, T] \} \) be an \( m \)-dimensional fBm with Hurst parameter \( H > 3/4 \). Define

\[
\zeta_{k,n}^{ij} = n \int_{t_k}^{t_{k+1}} (B_s^j - B_{n\eta(s)}^j) \delta B_s^i,
\]

for \( i, j = 1, \ldots, m \) and \( k = 0, \ldots, n - 1 \), where we recall that \( t_k = \frac{kT}{n} \). Set also \( \zeta_{n,n} = 0 \). Let \( \lambda = \frac{1}{2} \), and \( \beta, p, p', q', f \) satisfy the assumptions in Proposition 7.1. Then

\[
\left\lfloor \frac{nt}{T} \right\rfloor \sum_{k=0}^{\lfloor nt/T \rfloor} f(t_k) \zeta_{k,n}^{ij} \to \frac{T}{2} \int_0^t f(s) \, dB_s^i
\]

in \( L^p \), where \( Z_t^{ij} \) is the generalized Rosenblatt process defined in Section 2.5.

Proof. To prove the corollary, it suffices to show that the conditions in Proposition 7.1 are all satisfied here. We have shown in Section 2.5 the \( L^2 \) convergence of \( g_n(t) = \sum_{k=0}^{\lfloor nt/T \rfloor} \zeta_{k,n}^{ij} \) to \( Z_t^{ij} \). This convergence also holds in \( L^p \) due to the equivalence of all the \( L^p \)-norms in a finite Wiener chaos. Applying (A.8) in Lemma A.4 with \( F \equiv 1 \) and taking into account that \( \gamma_n = n \) when \( H > \frac{3}{4} \), we obtain condition (ii) in Proposition 7.1 with \( \lambda = \frac{1}{2} \). \( \square \)

The following result will also be useful later.

Corollary 7.2. Let \( B = \{ B_t, t \in [0, T] \} \) be one-dimensional fBm with Hurst parameter \( H \in (\frac{1}{2}, 1) \). Define

(7.12)

\[
\zeta_{k,n} = \int_{t_k}^{t_{k+1}} (s - \eta(s)) \, dB_s,
\]

for \( k = 0, \ldots, n - 1 \). Set also \( \zeta_{n,n} = 0 \). Let \( \lambda = H \), and \( \beta, p, p', q', f \) satisfy the assumptions in Proposition 7.1. Then for each \( t \in [0, T] \),

\[
n \sum_{k=0}^{\lfloor nt/T \rfloor} f(t_k) \zeta_{k,n} \to \frac{T}{2} \int_0^t f(s) \, dB_s,
\]

in \( L^p \), as \( n \) tends to infinity. This convergence still holds true when we replace the above \( \zeta_{k,n} \) by

\[
\tilde{\zeta}_{k,n} = \int_{t_k}^{t_{k+1}} (B_s - B_{n\eta(s)}) \, ds.
\]
Proof. As before, to prove the corollary it suffices to show that the conditions in Proposition 7.1 are all satisfied here. Let us first consider the convergence for $\zeta_{k,n}$. Set

$$g_n(t) := n \sum_{k=0}^{\lfloor nt/T \rfloor} \zeta_{k,n},$$

where $\zeta_{k,n}$ is defined in (7.12). Condition (ii) follows from estimate (A.4) in Lemma A.3 by taking $F \equiv 1$ and $\nu = 1$. The covariance of the process $g_n$ is given by

$$E(g_n(t)g_{n'}(t)) = \alpha_Hn\int_0^t \int_0^t (u - \eta_n(u))(v - \eta_{n'}(v))\mu(du \, dv)$$

$$\to \frac{T^2}{4} \alpha_H \int_0^t \int_0^t |u - v|^{2H-2} \, du \, dv$$

$$= \frac{T^2}{4} t^{2H}$$

as $n, n' \to \infty$, which implies that $g_n(t)$ is a Cauchy sequence in $L^2$. Here $\eta_n(t) = \frac{T}{n} i$ when $\frac{T}{n} i \leq t < \frac{T}{n} (i + 1)$ and $\eta_{n'}(t) = \frac{T}{n'} j$ when $\frac{T}{n'} j \leq t < \frac{T}{n'} (j + 1)$. In fact, we can also calculate the kernel of the limit of $z_n(t)$. Suppose that $\phi_n \in H$ satisfies $g_n(t) = \delta(\phi_n(t))$. Then for any $\psi \in H$,

$$\langle n\phi_n, \psi \rangle_H = n\alpha_H \int_0^T \int_0^{\eta(t)} (u - \eta(u))\psi(u)\, du \, dv$$

$$\to \frac{T}{2} \langle \psi, 1_{[0,T]} \rangle_H,$$

as $n \to +\infty$. This implies that the kernel of the limit of $g_n(t)$ is $\frac{T}{2} 1_{[0,T]}$; in other words, the random variable $g_n(t)$ converges in $L^2$ to $\frac{T}{2} B_t$.

The convergence result for $\tilde{\zeta}_{k,n}$ can be shown by noticing that

$$\tilde{\zeta}_{k,n} = \int_{t_k}^{t_{k+1}} (B_s - B_{\eta(s)}) \, ds = \frac{T}{n} (B_{t_{k+1}} - B_{t_k}) - \int_{t_k}^{t_{k+1}} (s - \eta(s)) \, dB_s.$$

This completes the proof of the corollary. $\square$

8. Asymptotic error of the modified Euler scheme in case $H \in \left(\frac{3}{4}, 1\right)$. The limit theorems for weighted sums proved in the previous section allow us to derive the $L^p$-limit of the quantity $n(X_t - X^n_t)$ in the case $H \in \left(\frac{3}{4}, 1\right)$.

Theorem 8.1. Let $H \in \left(\frac{3}{4}, 1\right)$. Suppose that $X$ and $X^n$ are defined by (1.1) and (1.3), respectively. Let $Z^{ij}$, $i, j = 1, \ldots, m$ be the matrix-valued generalized Rosenblatt process defined in Section 2.5. Assume $\sigma \in C_b^5(\mathbb{R}^d; \mathbb{R}^{d \times m})$.
and \( b \in C^4_b(\mathbb{R}^d, \mathbb{R}^d) \). Then
\[
n(X_t - X^n_t) \to U_t
\]
in \( L^p(\Omega) \) as \( n \) tends to infinity, where \( \{\tilde{U}_t, t \in [0, T]\} \) is the solution of the following linear stochastic differential equation:
\[
\tilde{U}_t = \int_0^t \nabla b(X_s) \tilde{U}_s ds + \sum_{j=1}^m \int_0^t \nabla \sigma^j(X_s) dB^j_s
\]
\[
+ \sum_{i,j=1}^m \int_0^t \langle \nabla \sigma^i \sigma^j \rangle(X_s) dZ^i_j
\]
\[
+ \frac{T}{2} \int_0^t (\nabla b b)(X_s) ds + \frac{T}{2} \int_0^t (\nabla b \sigma)(X_s) dB_s
\]
\[
+ \frac{T}{2} \sum_{i,j=1}^m \int_0^t (\nabla \sigma^i b)(X_s) dB^j_s.
\]

**Proof.** Recall the decomposition \( Y_t = X_t - X^n_t \) given in (4.7) and (4.11). We have shown that \( nI_{13}(t), nI_{4,j}(t), nE_{1,j}(t) \) and \( nE_{3,j}(t) \) converge in \( L^p \) to zero for each \( t \in [0, T] \). It remains to show the \( L^p \) convergence of \( nI_{11}(t), nI_{2,j}(t) \) and \( nE_{2,j}(t) \) and identify their limits.

**Step 1.** Recall \( \tilde{E}_{2,j}(t) \) is defined in (6.6). It has been shown in the proof of Theorem 6.1 that \( n(E_{2,j}(t) - \tilde{E}_{2,j}(t)) \) converges to zero in \( L^p \). On the other hand, applying Corollary 7.1 to \( n\tilde{E}_{2,j}(t) \) yields
\[
n\tilde{E}_{2,j}(t) \to \sum_{i=1}^m \int_0^t \Lambda_t \Gamma_s (\nabla \sigma^i \sigma^j)(X_s) dZ^i_j \quad \text{in} \ L^p.
\]
Therefore, \( nE_{2,j}(t) \) converges in \( L^p \), and the limit is the same as \( n\tilde{E}_{2,j}(t) \).

**Step 2.** Denote
\[
\tilde{I}_{2,j}(t) = \Lambda_t \sum_{k=0}^{\lfloor nt/T \rfloor} \Gamma_{t_k} (\nabla \sigma^j b)(X_{t_k}) \int_{t_k}^{t_{k+1} \wedge t} (s - \eta(s)) dB^j_s,
\]
for \( t \in [0, T] \) [as before, we define \( t_{n+1} = \frac{T}{n} (n + 1) \)]. Applying Corollary 7.2 to \( n\tilde{I}_{2,j}(t) \) yields
\[
n\tilde{I}_{2,j}(t) \to \frac{T}{2} \int_0^t \Lambda_t \Gamma_s (\nabla \sigma^j b)(X_s) dB^j_s \quad \text{in} \ L^p.
\]
We want to show that \( nI_{2,j}(t) \) and \( n\tilde{I}_{2,j}(t) \) have the same limit in \( L^p \). Write
\[
n(I_{2,j}(t) - \tilde{I}_{2,j}(t))
The theorem follows from the fact that the process defined, for each \( n \), converges in \( 1 \) of the first term.

Step 3. Following the lines in step 2 we can show that \( nI_{12,j}(t) \) converges in \( L^p \) to
\[
\frac{T}{2} \int_0^t \Lambda_t \Gamma_s(\nabla b \sigma^j)(X_s) d\tilde{B}_s^j.
\]
Instead of (A.4) and (A.6) in step 2, we need to use estimates (A.5) and (A.7) here.

Similarly, it can be shown that \( nI_{11} \) converges in \( L^p \) to
\[
\frac{T}{2} \int_0^t \Lambda_t \Gamma_s(\nabla b \sigma)(X_s) ds.
\]

Step 4. We have shown that \( n(X_t - X^n_t) \) converges in \( L^p \) to \( U_t \), where we define, for each \( t \in [0, T] \),
\[
U_t = \sum_{i,j=1}^m \int_0^t \Lambda_t \Gamma_s(\nabla \sigma^i \sigma^j)(X_s) dZ_s^{ij} + \frac{T}{2} \int_0^t \Lambda_t \Gamma_s(\nabla b \sigma)(X_s) ds
+ \frac{T}{2} \int_0^t \Lambda_t \Gamma_s(\nabla b \sigma)(X_s) dB_s + \frac{T}{2} \sum_{j=1}^m \int_0^t \Lambda_t \Gamma_s(\nabla \sigma^j b)(X_s) d\tilde{B}_s^j.
\]
The theorem follows from the fact that the process \( U \) satisfies equation (8.1).

\( \Box \)

9. Weak approximation of the modified Euler scheme. The next result provides the weak rate of convergence for the modified Euler scheme (1.3).

**Theorem 9.1.** Let \( X \) and \( X^n \) be the solution to equations (1.1) and (1.3), respectively. Suppose that \( b \in C^3_0(\mathbb{R}^d; \mathbb{R}^d) \), \( \sigma \in C^4_0(\mathbb{R}^d; \mathbb{R}^{d \times m}) \). Then for any function \( f \in C^0_b(\mathbb{R}^d) \) there exists a constant \( C \) independent of \( n \) such that
\[
\sup_{0 \leq t \leq T} \left| \mathbb{E}[f(X_t)] - \mathbb{E}[f(X^n_t)] \right| \leq Cn^{-1}.
\]
If we further assume that \( b \in C^4 \), \( \sigma \in C^5 \) and \( f \in C^4 \), then for each \( t \in [0, T] \), the sequence

\[
n \{ \mathbb{E}[f(X_t)] - \mathbb{E}[f(X^n_t)] \}, \quad n \in \mathbb{N},
\]

converges as \( n \) tends to infinity, and the limit is equal to the sum of the following two quantities:

\[
\frac{\alpha_H^2 T}{2} \sum_{j=1}^{m} \int_0^t \int_0^t \mathbb{E}\{D^i_tD^j_t[\nabla f(X_t)\Lambda_t \Gamma_s(\nabla \sigma^j \sigma^i)(X_s)] \}
\]

and

\[
\frac{T}{2} \mathbb{E} \left\{ \nabla f(X_t) \Lambda_t \left[ \int_0^t \Gamma_s(\nabla b)(X_s) \, ds + \int_0^t \Gamma_s(\nabla b\sigma)(X_s) \, dB_s 
\right.
\]

\[
\left. + \sum_{j=1}^{m} \int_0^t \Gamma_s(\nabla \sigma^j b)(X_s) \, dB_s^j \right\}.
\]

**Proof.** We use again decompositions (4.7) and (4.11) of \( Y_t = X_t - X^n_t \), \( t \in [0, T] \), and we continue to use the notation there. Given a function \( f \in C^3_b(\mathbb{R}^d) \), we can write

\[
n \{ \mathbb{E}[f(X_t)] - \mathbb{E}[f(X^n_t)] \} = n \int_0^1 \mathbb{E}[\nabla f(Z^n_t)Y_t] \, d\theta,
\]

where we denote \( Z^n_t = \theta X_t + (1 - \theta) X^n_t \), \( 0 \leq t \leq T \).

**Step 1.** In this step, we show that \( \sup_{0 \leq t \leq T} |\mathbb{E}[\nabla f(Z^n_t)Y_t]| \leq C n^{-1} \), which implies (9.1). From estimates (4.9) and (4.10) it follows that this inequality is true when \( Y \) is replaced by \( I_{11}, I_{13}, I_{21,2}, I_{2,2} \) or \( I_{4,1} \). Therefore, it suffices to show that \( |\mathbb{E}[\nabla f(Z^n_t)E_{i,j}(t)]| \leq C n^{-1} \) for \( i = 1, 2, 3 \) and \( j = 1, \ldots, m \), where \( E_{i,j}(t) \) are defined in Theorem 4.1 step 3. Consider first the term \( i = 2 \). The use of expression (4.12) and an application of the integration by parts formula yield

\[
\mathbb{E}[\nabla f(Z^n_t)E_{2,j}(t)]
\]

\[
= \mathbb{E} \left[ \nabla f(Z^n_t) \Lambda_t^n \sum_{i=1}^{m} \sum_{k=0}^{[nt/T]} F_{t_1}^{n,i,j} \int_{t_k}^{t_{k+1}} \delta B_u^i \delta B_s^j \right]
\]

\[
= \alpha_H^2 \sum_{i=1}^{m} \sum_{k=0}^{[nt/T]} \mathbb{E} \left[ \int_0^t \int_{t_k}^{t_{k+1}} \int_0^t \int_{t_k}^{s} D^i_tD^j_t[\nabla f(Z^n_t)\Lambda_t^n F_{t_k}^{n,i,j}] \right.
\]

\[
\times \mu(du)\mu(ds)\mu(ds) \right],
\]
where we recall that $F^n_{t_n,i,j} = \Gamma^n_t(\nabla \sigma^j \sigma^i)(X^n_t)$. [As before, in the above equation we set $t_{n+1} = \frac{T}{n}(n+1).$] Therefore,

$$\left|\mathbb{E}[\nabla f(Z_t^0)E_{2,j}(t)]\right| \leq C \sum_{k=0}^{n-1} \int_{t_k}^{t} \int_{t_k}^{t} \mu(du dv) \mu(dr ds)$$

$$\leq Cn^{-1}.$$  

For the term containing $E_{1,j}$ we can write

$$\mathbb{E}[\nabla f(Z_t^0)E_{1,j}(t)] = \sum_{i=1}^{m} \mathbb{E}\left[ \int_0^t H^n_{s,i,j}(B^i_s - B^i_{\eta(s)}) dB^j_s \right],$$

where $H^n_{s,i,j} = \nabla f(Z_t^0)A^n_t[\Gamma^n_{s,i,j}(s) - \Gamma^n_{\eta(s)}(\nabla \sigma^j \sigma^i)(X^n_{\eta(s)})].$ An application of the relation between the Skorohod and path-wise integrals (2.9) yields

$$\mathbb{E}\left[ \int_0^t H^n_{s,i,j}(B^i_s - B^i_{\eta(s)}) dB^j_s \right]$$

$$= \alpha_H \int_0^T \int_0^t \mathbb{E}[\int_0^s D^i_u H^n_{s,i,j}(B^i_s - B^i_{\eta(s)})] |s - u|^{2H-2} ds du$$

$$= \alpha_H \int_0^T \int_0^t \mathbb{E}[\int_0^s D^i_u H^n_{s,i,j}(B^i_s - B^i_{\eta(s)})] |s - u|^{2H-2} ds du$$

$$+ \alpha_H \int_0^T \int_0^t \mathbb{E}[H^n_{s,i,j}] 1_{[\eta(s),s]}(u) \delta_{ij} |s - u|^{2H-2} ds du$$

$$:= A_1 + A_2.$$  

By the integration by parts we see that $A_1$ is equal to

$$\alpha_H \int_0^T \int_0^t \int_0^s \mathbb{E}[D^i_u D^j_v H^n_{s,i,j}] 1_{[\eta(s),s]}(v) |v - r|^{2H-2} |s - u|^{2H-2} dv dr ds du.$$  

Using $\sup_{r,u,s} |\mathbb{E}[D^i_u D^j_v H^n_{s,i,j}]| \leq Cn^{-\beta}$ for any $\frac{1}{2} < \beta < H$ we obtain

$$|A_1| \leq Cn^{-1-\beta}.$$  

On the other hand, it is easy to show by the definitions of $\Gamma^n$, $X^n$ and $X$ that the quantity $[\Gamma^n_{s,i,j}(s) - \Gamma^n_{\eta(s)}(\nabla \sigma^j \sigma^i)(X^n_{\eta(s)})]$ can be expressed as the sum of integrals over the interval $[\eta(s),s].$ So by applying (2.9) and integration by parts we can show that $|\mathbb{E}[H^n_{s,i,j}]| \leq Cn^{-1},$ which implies

$$|A_2| \leq Cn^{-2H}.$$  

From (9.5) and (9.6) we conclude that $|\mathbb{E}[\nabla f(Z_t^0)E_{1,j}(t)]| \leq Cn^{-1}.$ Finally, for the term containing $E_{3,j}$ we have

$$\mathbb{E}[\nabla f(Z_t^0)E_{3,j}(t)] = \int_0^t \mathbb{E}[J^n_{s,i,j}] (s - \eta(s))^{2H-1} ds,$$
where \( J_{\alpha}^{n,i,j} = H \nabla f(Z^\theta_t) \Lambda_t \Gamma_{\alpha}^{n} (\eta_j(s)) - \Gamma_{\alpha}^{n}(s) \sigma_j^{n}(s) \). By expressing the term \((\Gamma_{\alpha}^{n}(\eta_j(s)) - \Gamma_{\alpha}^{n}(s))\) as the sum of integrals over the interval \([\eta(s), s]\) and then applying (2.9) and integration by parts, we can show that \( \sup_{s \in [0,T]} \mathbb{E}[|J_{\alpha}^{n,i,j}|] \leq Cn^{-1} \). This implies

\[
|\mathbb{E}[^n{\nabla f(Z^\theta_t) E_{j,j}}(t)]| \leq Cn^{-2H},
\]

which completes the proof of (9.1).

**Step 2.** Now we show the second part of the theorem. From estimates (4.9), (4.10), (9.5), (9.6) and (9.7) we see that the expression \( n \int_{0}^{1} \mathbb{E}[\nabla f(Z^\theta_t) Y_t] \, dt \) converges to zero as \( n \) tends to infinity when \( Y_t \) is replaced by \( I_{13}(t) \), \( I_{1,j}(t) \), \( E_{1,j}(t) \) or \( E_{3,j}(t) \). Therefore, it suffices to consider \( n \int_{0}^{1} \mathbb{E}[\nabla f(Z^\theta_t) Y_t] \, dt \) when \( Y_t \) is replaced by the remaining terms in the decomposition of \( Y_t \).

Consider first the term \( E_{2,j}(t) \), and denote

\[
G_{s,r,v}^{i,j} = D_{s}^{i} D_{r}^{j}[\nabla f(X_t) \Lambda_t \Gamma_{s}(\sigma_j^{i} \sigma_j^{i})](X_s)].
\]

It is clear that

\[
n \alpha_H^2 \sum_{i,j=1}^{m} \sum_{k=0}^{[nt/T]} \int_{t_k}^{t(t_{k+1} \wedge t)} \int_{t_k}^{s} G_{s,r,v}^{i,j} \mathbb{E}^{i,j}(du \, dv) \mu(ds \, dr)
\]

\[
\rightarrow \frac{\alpha_H^2 T}{2} \sum_{i,j=1}^{m} \int_{0}^{t} \int_{0}^{t} \int_{0}^{t} G_{s,r,v}^{i,j} |s-v|^{2H-2} |r-s|^{2H-2} ds \, dv \, dr,
\]

almost surely. Therefore, by the dominated convergence theorem, the expectation of the left-hand side of the above expression converges to the expectation of the right-hand side, which is term (9.2). From Lemma 4.1, we have

\[
\|D_{s}^{i} D_{r}^{j}[\nabla f(Z^\theta_t) \Lambda_t F_{\alpha}^{i,n,i,j}] - D_{s}^{i} D_{r}^{j}[\nabla f(X_t) \Lambda_t \Gamma_{s}(\sigma_j^{i} \sigma_j^{i})](X_{s})]\|_p
\]

\[
\leq Cn^{-1-2\beta},
\]

which, together with equation (9.4), implies that \( n \sum_{j=1}^{m} \mathbb{E}[\nabla f(Z^\theta_t) E_{2,j}(t)] \) converges to the same limit as the expectation of the left-hand side of (9.8).

The results in steps 2 and 3 of the proof of Theorem 8.1 imply that the terms \( n \mathbb{E}[\nabla f(Z^\theta_t) I_{11}(t)] \), \( n \mathbb{E}[\nabla f(Z^\theta_t) I_{12,j}(t)] \) and \( n \mathbb{E}[\nabla f(Z^\theta_t) \sum_{j=1}^{m} I_{2,j}(t)] \) converge to the second, third and fourth term in (9.3), respectively. For example, let us consider \( n \mathbb{E}[\nabla f(Z^\theta_t) \sum_{j=1}^{m} I_{2,j}(t)] \). We have shown in Theorem 8.1 that

\[
n I_{2,j}(t) \rightarrow \frac{T}{2} \Lambda_t \int_{0}^{t} \Gamma_{s}(\sigma_j^{i} b)(X_s) \, dB_{s}^{j}
\]
in $L^p$ for any $p \geq 1$. So it follows from the Hölder inequality that
\[
\left| \mathbb{E} \left[ n \nabla f(Z^\theta_t) I_{2,j}(t) - \nabla f(X_t) \frac{T}{2} \Lambda_t \int_0^t \Gamma_s(\nabla \sigma^j b)(X_s) dB_s^j \right] \right| \to 0
\]
as $n \to \infty$. The other two terms can be studied in similar way. This completes the proof of the theorem. \(\square\)

Remark 9.1. Theorem 9.1 may be used to construct a Richard extrapolation scheme with error bound $o(n^{-1})$.

10. Rate of convergence for the Euler scheme. In this section, we apply our approach based on Malliavin calculus developed in Section 4 to study the rate of convergence of the naive Euler scheme defined in (1.2). Our first result is the rate of the strong convergence of the naive Euler scheme. As we will see, the weak rate of convergence and the rate of strong convergence are the same for the naive Euler scheme. We still use $X^n$ to represent the naive Euler scheme (1.2). This will not cause confusion since we will only deal with this scheme in this section.

Theorem 10.1. Let $X$ and $X^n$ be the processes defined in (1.1) and (1.2), respectively. Suppose that $b \in C^1_b(\mathbb{R}^d; \mathbb{R}^d)$ and $\sigma \in C^2_b(\mathbb{R}^d; \mathbb{R}^{d \times m})$. Then for each $p \geq 1$, we have
\[
n^{2H-1} \sup_{t \in [0,T]} \mathbb{E}(|X_t - X^n_t|^p)^{1/p} \leq C.
\]
If we assume $b \in C^3_b(\mathbb{R}^d; \mathbb{R}^d)$ and $\sigma \in C^4_b(\mathbb{R}^d; \mathbb{R}^{d \times m})$, then as $n$ tends to infinity,
\[
n^{2H-1}(X_t - X^n_t) \to \frac{T^{2H-1}}{2} \sum_{j=1}^m \Lambda_t \Gamma_s(\nabla \sigma^j \sigma^j)(X_s) ds,
\]
where $\Lambda$ is the solution to linear equation (4.16) and $\Gamma_t = \Lambda^{-1}_t$, and the convergence holds in $L^p$ for all $p \geq 1$.

Proof. We let $Y_t = X_t - X^n_t$, $t \in [0,T]$. Then as in the proof of Theorem 4.1, we can derive the decomposition of $Y_t$
\[
Y_t = \Lambda^n \int_0^t \Gamma^n_{s} b_3(s) \left[ b(X^n_{\eta(s)})(s - \eta(s)) + \sum_{l=1}^m \sigma^l(X^n_{\eta(s)})(B^l_s - B^l_{\eta(s)}) \right] ds
+ \sum_{j=1}^m \int_0^t \Lambda^n \Gamma^n_{s} b_2^j(s)(s - \eta(s)) dB^j_s
\]
\[ + \sum_{i,j=1}^{m} \int_{0}^{t} \Lambda_{t}^{n} \Gamma_{s}^{n} \sigma_{2}^{j,i}(s)(B_{s}^{i} - B_{\eta(s)}^{i}) dB_{s}^{j} \]
\[ = I_{1}(t) + I_{2}(t) + I_{3}(t) + I_{4}(t), \]

where \( \Lambda^{n}, \Gamma^{n}, b_{2}^{i}(s), \sigma_{2}^{j,i}(s) \) and \( b_{3}(s) \) are the same terms as those defined in the proof of Theorem 4.1 with the scheme \( X^{n} \) replaced by the classical Euler scheme (1.2).

It is clear that \( \|I_{1}(t)\|_{p} \leq Cn^{-1} \). On the other hand, estimates (A.4) and (A.5) of Lemma A.3 imply that \( \|I_{2}(t)\|_{p} \leq Cn^{-1} \) and \( \|I_{3}(t)\|_{p} \leq Cn^{-1} \). Finally, as in the proof of (A.15) in Lemma A.5 we obtain \( \|I_{4}(t)\|_{p} \leq Cn^{1-2H} \). This completes the proof of the first part of the theorem.

Applying the integration by parts to \( I_{4}(t) \) yields
\[ \int_{0}^{t} \Lambda_{t}^{n} \Gamma_{s}^{n} \sigma_{2}^{j,i}(s)(B_{s}^{i} - B_{\eta(s)}^{i}) dB_{s}^{j} \]
\[ = \int_{0}^{t} \Lambda_{t}^{n} \Gamma_{s}^{n} \sigma_{2}^{j,i}(s)(B_{s}^{i} - B_{\eta(s)}^{i}) \delta B_{s}^{j} \]
\[ + \alpha_{H} \int_{0}^{t} \int_{0}^{t} D_{r}[\Lambda_{t}^{n} \Gamma_{s}^{n} \sigma_{2}^{j,i}(s)](B_{s}^{i} - B_{\eta(s)}^{i}) \mu(ds, dr) \]
\[ + \delta_{ij} \alpha_{H} \int_{0}^{t} \int_{0}^{t} \Lambda_{t}^{n} \Gamma_{s}^{n} \sigma_{2}^{j,i}(s)1_{[\eta(s),s]}(r) \mu(ds, dr) \]
\[ =: A_{1}^{n}(t) + A_{2}^{n}(t) + A_{3}^{n}(t). \]

From (A.8) we have \( \|A_{1}^{n}(t)\|_{p} \leq Cn^{-1-H} \). Applying (A.5) with \( F_{u} \) replaced by
\[ \int_{0}^{t} D_{r}[\Lambda_{t}^{n} \Gamma_{s}^{n} \sigma_{2}^{j,i}(s)]|r - u|^{2H-2} dr \]
we obtain \( \|A_{2}^{n}(t)\|_{p} \leq Cn^{-1} \). So it suffices to identify the limit of \( n^{2H-1}A_{3}^{n}(t) \) in \( L^{p} \). It follows from Lemma 4.1 and Remark 4.1 that
\[ \|\Lambda_{t}^{n} \Gamma_{s}^{n} \sigma_{2}^{j,i}(s) - \Lambda_{t} \Gamma_{s}(\nabla \sigma^{j} \sigma^{i})(X_{s})\|_{p} \leq Cn^{1-2\beta}. \]

Therefore, \( n^{2H-1}A_{3}^{n}(t) \), and the quantity
\[ n^{2H-1} \int_{0}^{t} \int_{0}^{t} \Lambda_{t} \Gamma_{s}(\nabla \sigma^{j} \sigma^{i})(X_{s})1_{[\eta(s),s]}(r) |r - s|^{2H-2} ds dr \]
converges to the same value in \( L^{p} \). The theorem now follows by noticing that
\[ n^{2H-1} \int_{0}^{t} \int_{0}^{t} \Lambda_{t} \Gamma_{s}(\nabla \sigma^{j} \sigma^{i})(X_{s})1_{[\eta(s),s]}(r) |r - s|^{2H-2} ds dr \]
EULER SCHEMES OF SDE DRIVEN BY FBM

\[ n^{2H-1} \int_0^t \Lambda_t \Gamma_s (\nabla \sigma^j \sigma^j)(X_s) \frac{(s - \eta(s))^{2H-1}}{2H - 1} ds \]

\[ \to \frac{T^{2H-1}}{2 \alpha_H} \int_0^t \Lambda_t \Gamma_s (\nabla \sigma^j \sigma^j)(X_s) ds, \]

in \( L^p \) for all \( p \geq 1 \). \( \square \)

As a consequence of the above theorem, we can deduce the following result.

**Corollary 10.1.** Let \( X \) and \( X^n \) be the processes defined in (1.1) and (1.2), respectively. Suppose that \( b \in C_b^3(\mathbb{R}^d; \mathbb{R}^d) \), \( \sigma \in C_b^4(\mathbb{R}^d; \mathbb{R}^{d \times m}) \) and \( f \in C_b^2(\mathbb{R}^d) \). Let \( \Lambda \) be defined in (4.16). Then we have the following \( L^p \)-convergence as \( n \to \infty \) for all \( p \geq 1 \):

\[ n^{2H-1} [f(X^n_t) - f(X_t)] \to \frac{T^{2H-1}}{2} \sum_{j=1}^m \int_0^t \nabla f(X_t) \Lambda_t \Gamma_s (\nabla \sigma^j \sigma^j)(X_s) ds. \]

**Proof.** We can write

\[ n^{2H-1} [f(X^n_t) - f(X_t)] = n^{2H-1} \left( \int_0^1 \nabla f(Z^\theta_t) d\theta \right) (X^n_t - X_t), \]

where we denote \( Z^\theta_t = \theta X_t + (1 - \theta)X^n_t, \ t \in [0, T] \). Then the result follows from Theorem 10.1, the convergence of \( X^n_t \) to \( X_t \) and the assumption on \( f \). \( \square \)

The above corollary implies the following weak approximation result:

\[ \lim_{n \to \infty} n^{2H-1} \{ \mathbb{E}[f(X_t)] - \mathbb{E}[f(X^n_t)] \} \]

\[ = \frac{T^{2H-1}}{2} \sum_{j=1}^m \int_0^t \mathbb{E}[\nabla f(X_t) \Lambda_t \Gamma_s (\nabla \sigma^j \sigma^j)(X_s)] ds. \]

**APPENDIX**

**A.1. Estimates of a Young integral.** In this section, we give an estimate on the pathwise integral using fractional calculus.

**Lemma A.1.** Let \( z = \{ z_t, t \in [0, T] \} \) be a Hölder continuous function with index \( \beta \in (0, 1) \). Suppose that \( f: \mathbb{R}^{l+m} \to \mathbb{R} \) is continuously differentiable. We denote by \( \nabla_x f \) the \( l \)-dimensional vector with coordinates \( \frac{\partial f}{\partial x^i} \), \( i = 1, \ldots, l \), and by \( \nabla_y f \) the \( m \)-dimensional vector with coordinates \( \frac{\partial f}{\partial x^{l+i}} \),
Consider processes \( x = \{ x_t, t \in [0,T] \} \) and \( y = \{ y_t, t \in [0,T] \} \) with dimensions \( l \) and \( m \), respectively, such that \( \| x \|_{0,T,\beta'} \) and \( \| y \|_{0,T,\beta''} \) are finite for each \( n \geq 1 \), where \( \beta' \in (0,1) \) is such that \( \beta' + \beta > 1 \). Then we have the following estimates:

(i) for any \( s, t \in [0,T] \) such that \( s \leq t \) and \( s = \eta(s) \), we have

\[
\left| \int_s^t f(x_r, y_{\eta(r)}) \, dz_r \right| \leq K_1 \sup_{r \in [s,t]} \| f(x_r, y_{\eta(r)}) \| z \|_{\beta}(t-s)^{\beta} \\
+ K_2 \sup_{r_1, r_2 \in [s,t]} \| \nabla_x f(x_{r_1}, y_{\eta(r_2)}) \| \| x \|_{s,t,\beta'} z \|_{\beta}(t-s)^{\beta+\beta'} \\
+ K_3 \sup_{r_1, r_2 \in [s,t]} \| \nabla_y f(x_{r_1}, y_{r_2}) \| \| y \|_{s,t,\beta'',n} z \|_{\beta}(t-s)^{\beta+\beta'},
\]

where the \( K_i, i = 1,2,3 \), are constants depending on \( \beta \) and \( \beta' \);

(ii) if the function \( f \) only depends on the first \( l \) variables, then the above estimate holds for all \( 0 \leq s \leq t \leq T \).

**Proof.** Take \( \alpha \) such that \( \beta' > \alpha > 1 - \beta \). Let \( s, t \in [0,T] \) be such that \( s = \eta(s) \) and \( s \leq t \). Applying the fractional integration by parts formula in Proposition 2.1, we obtain

\[
(A.1) \quad \left| \int_s^t f(x_r, y_{\eta(r)}) \, dz_r \right| \leq \int_s^t \| D_{s+}^{\alpha} f(x_r, y_{\eta(r)}) \| \| D_{t-}^{1-\alpha} (z_r - z_t) \| \, dr.
\]

By the definition of fractional differentiation in (2.3) and taking into account that \( \alpha + \beta - 1 > 0 \), we can show that

\[
(A.2) \quad \| D_{t-}^{1-\alpha} (z_r - z_t) \| \leq K_0 \| z \|_{\beta}(t-r)^{\alpha+\beta-1}, \quad s \leq r \leq t,
\]

where \( K_0 = \frac{\beta}{(\beta+\alpha-1)^\alpha} \). On the other hand, using (2.2) we obtain

\[
\| D_{s+}^{\alpha} f(x_r, y_{\eta(r)}) \| \\
\leq \frac{1}{\Gamma(1-\alpha)} \left[ \frac{\| f(x_r, y_{\eta(r)}) \|}{(r-s)^{\alpha}} + \alpha \int_s^r \frac{\| f(x_r, y_{\eta(r)}) - f(x_u, y_{\eta(u)}) \|}{(r-u)^{\alpha+1}} \, du \right] \\
\leq \frac{1}{\Gamma(1-\alpha)} \\
\times \left[ \sup_{r \in [s,t]} \| f(x_r, y_{\eta(r)}) \| (r-s)^{-\alpha} \\
+ \alpha \sup_{r_1, r_2 \in [s,t]} \| \nabla_x f(x_{r_1}, y_{\eta(r_2)}) \| \| x \|_{s,t,\beta'} \int_s^r (r-u)^{\beta'-\alpha-1} \, du \\
+ \alpha \sup_{r_1, r_2 \in [s,t]} \| \nabla_y f(x_{r_1}, y_{r_2}) \| \| y \|_{s,t,\beta'',n} \int_s^r \frac{\| \eta(r) - \eta(u) \|^{\beta'}}{(r-u)^{\alpha+1}} \, du \right].
\]
Inequalities (A.1), (A.3) and (A.2) together imply

\[
\left| \int_s^t f(x_r, y_{\eta(r)}) \, dz \right| \\
\leq \frac{1}{\Gamma(1 - \alpha)} \int_s^t \left[ \sup_{r \in [s,t]} |f(x_r, y_{\eta(r)})|(r - s)^{-\alpha} \right. \\
+ \alpha \sup_{r_1, r_2 \in [s,t]} |\nabla_x f(x_{r_1}, y_{\eta(r_2)})||x||s,t,\beta' \\\n\times \int_s^r (r - u)^{\beta' - \alpha - 1} \, du \\
+ \alpha \sup_{r_1, r_2 \in [s,t]} |\nabla_y f(x_{r_1}, y_{r_2})||y||s,t,\beta',n \\\n\left. \times \int_s^r \frac{\eta(r) - \eta(u)}{(r - u)^{\alpha + 1}} \, du \right] \\
\times K_0 \|z\|_\beta (t - r)^{\alpha + \beta - 1} \, dr \\
\leq K_1 \sup_{r \in [s,t]} |f(x_r, y_{\eta(r)})|\|z\|_\beta (t - s)^{\beta} \\
+ K_2 \sup_{r_1, r_2 \in [s,t]} |\nabla_x f(x_{r_1}, y_{\eta(r_2)})||x||s,t,\beta' \|z\|_\beta (t - s)^{\beta + \beta'} \\\n+ K_3 \sup_{r_1, r_2 \in [s,t]} |\nabla_y f(x_{r_1}, y_{r_2})||y||s,t,\beta',n \|z\|_\beta (t - s)^{\beta + \beta'},
\]

where \( K_1 = K_0 \frac{\Gamma(\alpha + \beta)}{\Gamma(1 + \alpha)} \), \( K_2 = K_0 \frac{\alpha \Gamma(\alpha + \beta) \Gamma(\beta' - \alpha)}{\Gamma(1 - \alpha) (\beta' + 1) (\beta' - \alpha)} \), \( K_3 = K_0 K_4 \frac{\alpha}{\Gamma(1 - \alpha)} \) and \( K_4 \) is the constant in Lemma A.2. This completes the proof. \( \square \)

**Lemma A.2.** Let \( \beta, \beta' \) and \( \alpha \) be such that \( \beta' > \alpha > 1 - \beta \). Then for any \( s, t \in [0, T] \) such that \( s < t \), \( s = \eta(s) \), there exists a constant \( K_4 \) depending on \( \alpha, \beta \) and \( T \), such that

\[
\int_s^t (t - r)^{\alpha + \beta - 1} \int_s^r \frac{\eta(r) - \eta(u)|^\beta}{(r - u)^{\alpha + 1}} \, du \, dr \leq K_4 (t - s)^{\beta + \beta'}.
\]

**Proof.** Without loss of generality, we let \( T = 1 \). Note that when \( \eta(s) = s < t \leq \eta(s) + \frac{1}{n} \), the double integral equals zero. In the following we will assume \( t > \eta(s) + \frac{1}{n} \).

We first write

\[
\int_s^t (t - r)^{\alpha + \beta - 1} \int_s^r \frac{\eta(r) - \eta(u)|^\beta}{(r - u)^{\alpha + 1}} \, du \, dr
\]
Thus, we fix $n \in \mathbb{N}$ and consider the uniform partition on $[0,T]$. In this section we derive estimates for some specific Young and Skorohod integrals.

The lemma is now proved. □

A.2. Estimates for some special Young and Skorohod integrals. In this section we derive estimates for some specific Young and Skorohod integrals. We fix $n \in \mathbb{N}$ and consider the uniform partition on $[0,T]$.

Let $B = \{B_t, t \in [0,T]\}$ be a one-dimensional fBm with Hurst parameter $H > \frac{1}{2}$. Fix $\nu \geq 0$ and $p \geq \frac{1}{H}$. Let $F = \{F_t, t \in [0,T]\}$ be a stochastic process whose trajectories are Hölder continuous of order $\gamma > 1 - H$ and such that $F_t \in D^{1,q}$, $t \in [0,T]$, for some $q > p$. For any $\rho > 1$ we set

$$ F_{1,\rho} = \sup_{s,t \in [0,T]} (\|F_t\|_\rho \vee \|D_s F_t\|_\rho). $$
Then there exists a constant $C$ (independent of $F$) such that the following inequalities hold for all $0 \leq s < t \leq T$:

\begin{align}
(A.4) & \quad \left\| \int_s^t F_u(u - \eta(u))^\nu \, dB_u \right\|_p \leq C n^{-\nu} (t - s)^{H} F_{1,p}, \\
(A.5) & \quad \left\| \int_s^t F_u(B_u - B_{\eta(u)}) \, du \right\|_p \leq C n^{-1} (t - s)^{H} F_{1,q}.
\end{align}

**Proof of (A.4).** Applying (2.9) we can decompose the Young integral as the sum of a Skorohod integral plus a complementary term,

\begin{equation}
\int_s^t F_u(u - \eta(u))^\nu \, dB_u
\end{equation}

\begin{align}
(A.6) & \quad = \int_s^t F_u(u - \eta(u))^\nu \, \delta B_u \\
& \quad + \alpha_H \int_s^t \int_0^T (u - \eta(u))^\nu D_r F_u |r - u|^{2H-2} \, dr \, du.
\end{align}

It follows from (2.11) that the $L^p$-norm of the first integral of the right-hand side of (A.6) is bounded by $C n^{-\nu} (t - s)^{H} F_{1,p}$. On the other hand, from Minkowski’s inequality it follows that the $L^p$-norm of the second integral is less than or equal to $C n^{-1} (t - s)^{H} F_{1,q}$. These estimates imply (A.4) because $(t - s) \leq (t - s)^{H} T^{1-H}$. □

**Proof of (A.5).** If $t - s \leq \frac{1}{n}$, we can write

\begin{align}
\left\| \int_s^t F_u(B_u - B_{\eta(u)}) \, du \right\|_p & \leq \int_s^t \|F_u(B_u - B_{\eta(u)})\|_p \, du \\
& \leq C \sup_{t \in [0,T]} \|F_t\| q n^{-H} (t - s) \\
& \leq C \sup_{t \in [0,T]} \|F_t\| q n^{-1} (t - s)^{H},
\end{align}

where the first inequality follows from Minkowski’s inequality and the second one from Hölder’s inequality. Suppose that $t - s \geq \frac{1}{n}$. Applying Fubini’s theorem for the Young integral, we obtain

\begin{equation}
\int_s^t F_u(B_u - B_{\eta(u)}) \, du = \int_{\eta(s)}^t \left( \int_v^{\xi(v)} 1_{[v,t]}(u) F_u \, du \right) \, dB_v.
\end{equation}

Applying (A.4) with $\nu = 0$ we obtain

\begin{align}
\left\| \int_{\eta(s)}^t \left( \int_v^{\xi(v)} 1_{[v,t]}(u) F_u \, du \right) \, dB_v \right\|_p & \leq C (t - \eta(s))^H n^{-1} F_{1,p}
\end{align}
This completes the proof of (A.5). □

**Lemma A.4.** Let 
\[ B_t = \{ B_t, t \in [0,T] \} \]
be an \( m \)-dimensional fBm with Hurst parameter \( H > \frac{1}{2} \). Fix \( p \geq \frac{1}{H} \). Let \( F = \{ F_t, t \in [0,T] \} \) be a stochastic process such that \( F_t \in D_{2,q}, t \in [0,T] \), for some \( q > p \). For any \( \rho > 1 \) we set
\[
F_{2,\rho} = \sup_{r,s,t \in [0,T]} (\| F_t \|_\rho \vee \| D_s F_t \|_\rho \vee \| D_r D_s F_t \|_\rho).
\]
Set also
\[
F_\ast = \sup_{r,s,t \in [0,T]} (| F_t | \vee | D_s F_t | \vee | D_r D_s F_t |).
\]
Then there exists a constant \( C \) (independent of \( F \)) such that the following holds for all \( 0 \leq s < t \leq T, \ i,j = 1, \ldots, m \):
\[
(A.7) \quad H \left[ \sum_{k \in [nt/T]} F_{tk} \int_{tk}^{tk+1/\Delta t} \int_{tk}^u \delta B^j_u \delta B^i_u \right] \leq C n^{-1}(t-s)^{1/2} \| F_\ast \|_q,
\]
\[
(A.8) \quad \sum_{k \in [nt/T]} F_{tk} \int_{tk}^{tk+1/\Delta t} \int_{tk}^u \delta B^j_u \delta B^i_u \leq C n^{-H}(t-s)^H F_{2,q}.
\]

**Proof.** Using (2.8), we can write
\[
(A.10) \quad \sum_{k \in [nt/T]} F_{tk} \int_{tk}^{tk+1/\Delta t} \int_{tk}^u \delta B^j_u \delta B^i_u = \int_s^t F_{\eta(u)}(B^i_u - B^i_{\eta(u)}) \delta B^j_u + \alpha_H \int_s^t \int_0^T D^j_{\eta(u)}(B^i_u - B^i_{\eta(u)}) \mu(dr du).
\]
Applying (A.5) to the second integral of the right-hand side of (A.10) with \( F_u \) replaced by \( \int_0^T D^j_{\eta(u)} r - u \|^{2H-2} dr \) (notice that here we do not need the Hölder continuity of the integrand for the Young integral to be well defined) yields
\[
(A.11) \quad \leq C n^{-1}(t-s)^H F_{2,q} \sup_{u \in [0,T]} \int_0^T |r-u|^{2H-2} dr
\]
\[ \leq Cn^{-1}(t-s)^H F_{2,q}. \]

This implies both estimates (A.8) and (A.9).

Applying (2.8) to the first summand on the right-hand side of (A.10) yields

\[ \int_0^t F_u(B^i_u - B^i_{\eta(u)}) \delta B^j_u \]

(A.12)

\[ = \int_s^t \int_{\eta(u)}^u F_u \delta B^i_u \delta B^j_u + \alpha_H \int_s^t \left\{ \int_0^T \int_{\eta(u)}^u D^i_u F_u \mu(dr dv) \right\} \delta B^j_u. \]

Now we apply (2.11) to the second term of the right-hand side of (A.12), and we obtain

\[ \left\| \int_s^t \left\{ \int_0^T \int_{\eta(u)}^u D^i_u F_u \mu(dr dv) \right\} \delta B^j_u \right\|_p \]

(A.13)

\[ \leq C F_{2,p} \left\| \mathbf{1}_{[s,t]}(u) \int_0^T \int_{\eta(u)}^u \mu(dr dv) \right\|_{L^1/H([0,T])} \]

\[ \leq C F_{2,p} n^{-1} (t-s)^H. \]

Again, this inequality implies both estimates (A.8) and (A.9).

To derive (A.8) we need a more accurate estimate. Meyer’s inequality implies that

\[ \| I_{s,t} \|_p \leq C F_{2,p} \| \mathbf{1}_{[s,t]}(u) \mathbf{1}_{[\eta(u),u]}(v) \|_{L^{1/H}([0,T]^2)} \]

\[ \leq C F_{2,p} n^{-H} (t-s)^H, \]

which completes the proof of (A.9).

To derive (A.8) we need a more accurate estimate.

\[ \| I_{s,t} \|_p \leq C \left\| \mathbf{1}_{[s,t]}(u) \mathbf{1}_{[\eta(u),u]}(v) F_u \right\|_{H^@2} \]

\[ + \left\| \mathbf{1}_{[s,t]}(u) \mathbf{1}_{[\eta(u),u]}(v) D_r F_u \right\|_{H^@3} \]

\[ + \left\| \mathbf{1}_{[s,t]}(u) \mathbf{1}_{[\eta(u),u]}(v) D_r D_r F_u \right\|_{H^@4} \]

\[ \leq C \| F_u \|_p \| \mathbf{1}_{[s,t]}(u) \mathbf{1}_{[\eta(u),u]}(v) \|_{H^@2}. \]

Therefore, to complete the proof, it suffices to show that

\[ \| \mathbf{1}_{[s,t]}(u) \mathbf{1}_{[\eta(u),u]}(v) \|_{H^@2}^2 \]

(A.14)

\[ = \alpha_H^2 \int_s^t \int_s^u \int_{\eta(u')} \int_{\eta(u)} \mu(dv dv') \mu(du du') \]

\[ \leq (t-s) \gamma_n^{-2}. \]
In the case \( t - s \geq \frac{1}{n} \),
\[
\int_s^t \int_s^t \mu(dv dv') \int_s^u \int_s^u \mu(du du')
\leq \sum_{k,k'=[n/T]}^{nt/T} \sum_{p=1-n}^{n-1} \int_{tk}^{tk'+1} \int_{tk}^{tk'} \int_{tk}^{tk'+1} \int_{tk}^{tk'} \mu(du dv dv' du')
\leq \sum_{k=[ns/T]}^{nt/T} \sum_{p=1-n}^{n-1} \int_{tk}^{tk+p} \int_{tk}^{tk+p} \int_{tk+p}^{tk+p} \int_{tk+p}^{tk+p} \mu(du dv dv' du')
= n^{-4H} \sum_{k=[ns/T]}^{nt/T} \sum_{p=1-n}^{n-1} Q(p)
\leq C(t-s)^{-n^2},
\]
where we recall that \( Q(p) \) is defined in Section 2.4, and inequality (A.14) follows.

In the case \( t - s \leq \frac{1}{n} \), we have the raw estimate
\[
\int_s^t \int_s^t \int_s^u \int_s^u \mu(du dv dv' du') \leq \frac{1}{n^{2H}} \int_s^t \int_s^t \mu(du dv') = \frac{1}{n^{2H}} (t-s)^{2H}
\]
and
\[
n^{-2H} (t-s)^{2H} \leq (t-s)^{-n^2}.
\]
So (A.14) is also true for this case. The proof of the lemma is now complete.

\[ \square \]

**Lemma A.5.** Let \( B = \{B_t, t \in [0,T]\} \) be a one-dimensional fBm with Hurst parameter \( H > \frac{1}{2} \). Suppose that \( F = \{F_t, t \in [0,T]\}, G = \{G_t, t \in [0,T]\} \) are processes that are Hölder continuous of order \( \beta \in (\frac{1}{2}, H) \). Then there exists a constant \( C \) (not depending on \( F \) or \( G \)) such that for all \( 0 \leq s < t \leq T, \nu \geq 0, \)
\[
\left| \int_s^t F_u(G_u - G_{\eta(u)})(B_u - B_{\eta(u)}) dB_u \right|
\leq C(\|F\|_{\infty} + \|F\|_{\beta})\|G\|_{\beta}\|\beta\|^2_n n^{1-3\beta}(t-s)^{\beta}
\]
and
\[
\left| \int_s^t F_u(G_u - G_{\eta(u)})(u - \eta(u))^\nu dB_u \right|
\leq C(\|F\|_{\infty} + \|F\|_{\beta})\|G\|_{\beta}\|\beta\|^1_n n^{1-2\beta-\nu}(t-s)^{\beta}.
\]
Proof of (A.15). We assume first that $s, t \in [t_k, t_{k+1}]$ for some $k = 0, 1, \ldots, n - 1$. By Lemma A.1(ii),

$$
\left| \int_s^t F_u(G_u - G_{\eta(u)})(B_u - B_{\eta(u)}) dB_u \right|
\leq K_1 \sup_{u \in [s,t]} |F_u(G_u - G_{t_k})(B_u - B_{t_k})|||B||_\beta(t-s)^\beta
+ K_2 \sup_{u \in [s,t]} \left[ |F_u(G_u - G_{t_k})|||B||_\beta(t-s)^{2\beta}
+ |(G_u - G_{t_k})(B_u - B_{t_k})|||F||_\beta|||B||_\beta(t-s)^{2\beta}\right]
$$

(A.17)

where $\kappa_\beta(F, G) = (||F||_\infty + ||F||_\beta)|||G||_\beta|||B||_\beta^2$. In the general case, we can write

$$
\left| \int_s^t F_u(G_u - G_{\eta(u)})(B_u - B_{\eta(u)}) dB_u \right|
= \left| \left( \int_s^{\epsilon(s)} + \sum_{k=[ns/T]+1}^{[nt/T]} \int_{t_k}^{t_{k+1}} \int_{\eta(t)}^t \right) F_u(G_u - G_{\eta(u)})(B_u - B_{\eta(u)}) dB_u \right|
\leq C\kappa_\beta(F, G)n^{-2\beta}\left[ (\epsilon(s) - s)^\beta + (t - \eta(t))^\beta + \sum_{k=[ns/T]+1}^{[nt/T]} (T/n)^\beta \right]
\leq C\kappa_\beta(F, G)n^{-2\beta}[\epsilon(s) - s)^\beta + (t - \eta(t))^\beta + (\eta(t) - \epsilon(s))n^{1-\beta}]
\leq C\kappa_\beta(F, G)n^{1-3\beta}(t-s)^\beta,
$$

where the first inequality follows from (A.17). □

Proof of (A.16). This estimate can be proved by following the lines of the proof of (A.15) and noticing the fact that $(u - \eta(u))^\nu$ has finite $\nu$-Hölder seminorm on $(t_k, t_{k+1})$ for each $k = 1, \ldots, n - 1$. □

Acknowledgment. We wish to thank the referee for many useful comments and suggestions.
