1 INTRODUCTION

Archimedes computed the center of mass of several regions and solid bodies [Dijkstra 1955], and this fundamental physical notion may very well be due to him. He based his investigations of this concept on the notion of moment as it is used in his Law of the Lever. A hyperbolic version of this law was formulated in the nineteenth century leading to the notion of a hyperbolic center of mass of two point-masses [Andrade, Bonola]. In 1969 Perron extended the notions of mass and center of mass to arbitrary regions of hyperbolic space. In 1987 Gal’perin proposed an axiomatic definition of the center of mass of finite systems of point-masses in Euclidean, hyperbolic and elliptic n-dimensional spaces and proved its uniqueness. Ungar [2004] used the theory of gyrogroups to show that in hyperbolic geometry the center of mass of three point-masses of equal mass coincides with the point of intersection of the medians, a fact that had already been noted by Perron. Some information regarding the centroids of finite point sets in spherical spaces can be found in [Fog, Fabricius-Bjerre].

In this article we begin by offering yet another physical motivation for the hyperbolic Law of the Lever and summarize Perron’s treatment of the subjects of mass and centers of mass (centroids). The masses and centroids of several geometric objects are derived. Surprisingly, the hyperbolic mass formulas are quite similar to the Euclidean ones whereas, as is well known, the formulas for hyperbolic area and volume look nothing like their Euclidean analogs.

For general information regarding the hyperbolic plane the reader is referred to [Greenberg, Ratcliffe, Stahl2].
This article has the following structure:

Section 1: Introduction
Section 2: The Hyperbolic Law of the Lever
Section 3: A Summary of Perron’s Results
Section 4: Planar Examples
Section 5: Higher Dimensions
Section 6: Formulas of the Hyperbolic Triangle

2 THE HYPERBOLIC LAW OF THE LEVER

Many hyperbolic formulas can be obtained from their Euclidean analogs by the mere replacement of a length \( d \) by \( \sinh d \). The Law of Sines and the Theorems of Menelaus and Ceva (see Appendix) are cases in point. It therefore would make sense that for a lever in the hyperbolic plane a suitable definition of the moment of a force \( w \) acting perpendicularly at distance \( d \) from the fulcrum is

\[ w \sinh d. \]

Nevertheless, a more physical motivation is in order. We begin with an examination of the balanced weightless lever of Figure 1. This lever is pivoted at \( E \) and has masses of weights \( w_1 \) and \( w_2 \) at \( A \) and \( B \) respectively. By this is meant that there is a mass \( D \), off the lever, which exerts attractive forces \( \vec{w}_1 \) and \( \vec{w}_2 \) along the straight lines \( AD \) and \( BD \). Since this system is assumed to be in equilibrium, it follows that the resultant of the forces \( \vec{w}_1 \) and \( \vec{w}_2 \) acts along the straight line \( ED \). Neither the direction nor the intensity of the resultant are affected by the addition of a pair of equal but opposite forces \( \vec{f}_1 \) and \( \vec{f}_2 \) at \( A \) and \( B \). (Here and below we employ the convention that the magnitude of the vector \( \vec{v} \) is denoted by \( v \).) We assume that the common magnitude of \( f_1 \) and \( f_2 \) is large enough so that the lines of direction of the partial resultants \( \vec{r}_i = \vec{f}_i + \vec{w}_i, i = 1, 2 \), intersect in some point, say \( C \). Note that the quadrilateral \( ACBD \) lies in the hyperbolic plane whereas the parallelograms of forces at \( A \) and \( B \) lie in the respective Euclidean tangent planes. This is the standard operating procedure in mathematical physics.

It is now demonstrated that such a system in equilibrium must satisfy the equation

\[ F_1 \sinh c_1 = F_2 \sinh c_2 \]  \hspace{1cm} (1)

where each \( \vec{F}_i \) is the component of \( \vec{w}_i \) in the direction orthogonal to \( AB \). Indeed, it follows from several applications of both the Euclidean and the hyperbolic Laws of Sines that

\[
\frac{w_1 \sinh c_1}{w_2 \sinh c_2} = \frac{w_1 \sin \gamma_1 \cdot \frac{\sinh a}{\sin \alpha_1}}{w_2 \sin \gamma_2 \cdot \frac{\sinh b}{\sin \beta_2}} = \frac{w_1 \sin \gamma_1 \sinh a}{w_2 \sin \gamma_2 \sinh b} = \]
Figure 1:
Figure 2:

\[
\sin \gamma_1 \cdot \frac{w_1}{\sin \alpha_1} = \sin \gamma_1 \cdot \frac{f_1}{\sin \phi_1} = \sin \gamma_1 \cdot \frac{f_2}{\sin \phi_2} = \sin \gamma_1 \cdot \frac{\sin \epsilon_2}{\sin \gamma_1} = \frac{\sinh \epsilon_1}{\sinh \gamma_1} = \sin \gamma_2 \cdot \frac{\sinh \epsilon_2}{\sinh \gamma_2} = \frac{\sinh \theta_2}{\sinh \epsilon_2} = \frac{\sin \theta_2}{\sinh \epsilon_2}.
\]

and Eq’n (1) follows by cross-multiplication.

If we take the mass at $D$ out of the picture and stipulate that $\vec{F}_1$ and $\vec{F}_2$ are simply two forces that act perpendicularly to the lever $AB$ (Fig. 2) then it is makes sense to regard the quantities $F_1 \sinh c_1$ and $F_2 \sinh c_2$ as the respective moments of the forces $\vec{F}_1$ and $\vec{F}_2$ with respect to the pivot point $E$. This facilitates the derivation of the resultant of $\vec{F}_1$ and $\vec{F}_2$. Suppose $\vec{F}_3 \perp AB$ at $E$, and $c_1$, $c_2$ are such that

\[
F_1 \sinh c_1 = F_2 \sinh c_2 \quad \text{and} \quad F_3 = F_1 \cosh c_1 + F_2 \cosh c_2 \quad (2)
\]

Then the moments of $\vec{F}_3$ with respect to $A$ and $B$ are, respectively

\[
(F_1 \cosh c_1 + F_2 \cosh c_2) \sinh c_1 = F_2 \cosh c_1 \sinh c_2 + F_2 \sinh c_1 \cosh c_2 = F_2 \sinh(c_1 + c_2)
\]

and

\[
(F_1 \cosh c_1 + F_2 \cosh c_2) \sinh c_2 = F_1 \sinh(c_1 + c_2).
\]

Since the right hand sides of these two equations, are, respectively, the moments of $\vec{F}_2$ with respect to $A$ and the moment of $\vec{F}_1$ with respect to $B$, it follows that the equations of (2) do indeed imply equilibrium. Consequently, the reverse of $\vec{F}_3$ is indeed the resultant of $\vec{F}_1$ and $\vec{F}_2$. 
3 A SUMMARY OF PERRON’S RESULTS

The physical considerations of the previous section motivate the following formal definitions. A point-mass is an ordered pair \((X, x)\) where its location \(X\) is a point of hyperbolic space \(H^n\) and its weight \(x\) is a nonnegative real number. The (unsigned) moment of the point-mass \((X, x)\) with respect to the hyperplane \(\Pi\) is, respectively, \[M_\Pi(X, x) = x \sinh d(X, \Pi)\]

where \(d(X, \Pi)\) is the hyperbolic distance from \(X\) to \(\Pi\).

Given any two point-masses \((X, x)\) and \((Y, y)\), their center of mass or centroid \((X, x) \ast (Y, y)\) is the point-mass \((Z, z)\), where \(Z\) is that point between \(X\) and \(Y\) such that

\[x \sinh XZ = y \sinh YZ\]

and

\[z = x \cosh XZ + y \cosh YZ\]  \(\text{(3)}\)

Note that this means that the two point-masses have equal moments with respect to their centroid. Moreover, if \(X = Y\) then \((X, x) \ast (Y, y) = (X, x+y)\).

The (signed) moment of the finite point-mass system \(X = \{(X_i, x_i), i = 1, 2, 3, \ldots, n\}\) with respect to the oriented hyperplane \(\Pi\) is

\[M_\Pi(X) = \sum_{i=1}^{n} \sigma_\Pi(X_i) M_\Pi(X_i, x_i)\]

where \(\sigma_\Pi(X) = 1, -1, 0\) according as \(X\) is in the left half-space of \(m\), right half-space of \(\Pi\) or on \(\Pi\) itself. The finite point-mass system \(X\) is said to be balanced with respect to the oriented hyperplane \(\Pi\) provided

\[M_\Pi(X) = 0.\]

It is clear that if \(\Pi\) and \(\Pi'\) are reverses of each other, then for every finite system \(X\) we have

\[M_\Pi(X) = -M_{\Pi'}(X)\]

and

\[M_\Pi(X) = 0 \text{ if and only if } M_{\Pi'}(X) = 0\]

The following theorem was proved in [Perron] by means of the Weierstrass coordinates. A detailed synthetic proof can be found in [Stahl3]

**Theorem 3.1 (Perron)** Given a finite point-mass system \(X = \{(X_i, x_i), i = 1, 2, 3, \ldots, n\}\), there exists a unique point-mass

\[C(X) = (C, c)\]
such that $C(X)$ and $X$ have the same signed moment with respect to every oriented hyperplane. Moreover,

$$c = \sum_{i=1}^{n} x_i \cosh[d(C, X_i)]$$

and

$$c^2 = \sum_{i,j=1}^{n} x_i x_j \cosh[d(X_i, X_j)].$$

A region in hyperbolic space $H^n$ is a compact subset of $H^n$ of finite positive measure. A (weighted) solid $L$ in $H^n$ is a pair $(L, \lambda)$ where $L$ is an $n$-Lebesgue measurable region in $H^n$ and $\lambda$ is a continuous non-negative valued function on $L$ such that

$$\int_L \lambda(X) dV > 0$$

where $V$ is the volume element. The value $\lambda(X)$ is the density of $L$ at $X$. The solid is said to be uniform if its density is constant throughout $L$. When $n = 2$ it is customary to refer to weighted solids as laminae.

Let $\Pi$ be an oriented hyperplane. We define the moment of $L$ with respect to $\Pi$ as

$$M_{\Pi}(L) = \int_L \sigma_{\Pi}(X) \lambda(X) \sinh[d(X, \Pi)] dV.$$ 

The hyperplane $\Pi$ is said to balance the solid $L$ if $M_{\Pi}(L) = 0$. The following theorem is surmised in [Perron] by analogy with Theorem 3.1. A detailed and intrinsic proof can be found in [Stahl3].

**Theorem 3.2 (Perron)** Given a weighted solid $L = (L, \lambda)$ there exists a unique point

$$C(L) = (C, c)$$

such that $C(L)$ and $L$ have the same signed moments with respect to every oriented hyperplane. Moreover,

$$c = \text{mass}(L) = \int_L \lambda(X) \cosh[d(C, X)] dV$$

and

$$c^2 = \text{mass}(L)^2 = \int_L \int_L \lambda(X) \lambda(Y) \cosh[d(X, Y)] dV_X dV_Y.$$ 

In some cases the mass of a figure can be found by first evaluating the mass of its orbit under the action of a finite group (see Proposition 4.1, 4.2, and 4.3). This is facilitated by the following corollary and proposition.
Corollary 3.3 Two solids have the same moment with respect to every oriented hyperplane if and only if they have identical centroids.

A decomposition of $\mathcal{L}$ is a family of sets $\tilde{\mathcal{L}} = \{L_1, L_2, ..., L_n\}$ such that

$$ L = L_1 \cup L_2 \cup \cdots \cup L_n $$

where distinct $L_i$’s intersect in sets of measure 0.

Proposition 3.4 Let $\mathcal{L} = (L, \lambda)$ be a solid, $\tilde{\mathcal{L}} = \{L_1, L_2, ..., L_n\}$ a decomposition of $\mathcal{L}$ and set

$$ \mathcal{L}_i = (L_i, \lambda|_{L_i}), \quad i = 1, 2, ..., n. $$

Then

$$ C(\mathcal{L}) = C(\mathcal{L}_1) \ast C(\mathcal{L}_2) \ast \cdots \ast C(\mathcal{L}_n). $$

PROOF: It follows from Theorem 3.2 and the additivity of integrals that for any oriented hyperplane $\Pi$

$$ M_{\Pi}[C(\mathcal{L})] = M_{\Pi}(\mathcal{L}) = M_{\Pi}(\mathcal{L}_1) + M_{\Pi}(\mathcal{L}_2) + \cdots + M_{\Pi}(\mathcal{L}_n) $$

$$ = M_{\Pi}[C(\mathcal{L}_1)] + M_{\Pi}[C(\mathcal{L}_2)] + \cdots + M_{\Pi}[C(\mathcal{L}_n)] $$

$$ = M_{\Pi}[C(\mathcal{L}_1) \ast C(\mathcal{L}_2) \ast \cdots \ast C(\mathcal{L}_3)]. $$

The validity of the proposition now follows from the arbitrariness of $\Pi$, Theorem 3.2 and Proposition 3.3.

Q.E.D.

4 PLANAR EXAMPLES

Not surprisingly, we begin with a one dimensional figure.

Proposition 4.1 The centroid of a hyperbolic line segment of length $d$ and uniform density 1 is located at its midpoint and its mass is $2 \sinh(d/2)$.

PROOF: The first part follows from a symmetry argument. The second part is valid because

$$ 2 \int_0^{d/2} \cosh x dx = 2 \sinh(d/2). $$

Q.E.D.

Some of the subsequent examples are worked out in a specific model of hyperbolic geometry that is based on a general geodesic polar parametrization used by Gauss in [Gauss]. This Gaussian model presents the hyperbolic...
plane as a Riemannian geometry whose domain is the entire plane with polar coordinates \((\rho, \theta)\) and metric [Gauss, Ratcliffe, Stahl1]

\[ d\rho^2 + \sinh^2 \rho d\theta^2 \]

The geodesics of this metric are the Euclidean straight lines \(\theta = c\) and the curves

\[ \rho = \coth^{-1}(C \cos(\theta - \alpha)) \]

where \(\alpha\) is arbitrary and \(C > 1\). Here \(\coth^{-1}(C)\) is the distance from the origin to the geodesic and \(\alpha\) is the angle of inclination of the line through the origin and perpendicular to the geodesic in question. The area element of this metric is

\[ dA = \sinh \rho d\rho d\theta. \]

It is clear that mass is invariant under rigid motions and consequently the axes of reflections of a region contain its centroid. In particular the centroid of a uniform disk is located at its center.

**Proposition 4.2** The mass of a disk of uniform density 1 and hyperbolic radius \(r\) is

\[ \pi \sinh^2 r. \]

**PROOF:** We employ the Gauss model and assume that the disk is centered at the origin which coincides with its centroid. By the Theorem 3.2, the mass of this disk is

\[ \int_0^{2\pi} \int_0^r \cosh \rho \sinh \rho d\rho d\theta = \pi \sinh^2 r. \]

Q.E.D.

This formula is particularly interesting for the following reason. As was noted above, many hyperbolic formulas can be obtained from their Euclidean analogs by the heuristic means of replacing a certain length \(d\) by \(\sinh d\). One of the exceptions to this informal rule is the area of a circle of radius \(r\). The Euclidean formula is

\[ \pi r^2 \]

whereas the hyperbolic formula is

\[ 4\pi \sinh^2 \left(\frac{r}{2}\right). \]

Thus, it would seem that while in Euclidean geometry area and uniform mass are essentially equivalent, in hyperbolic geometry, where they are distinct, sometimes it is the notion of mass that is better behaved (by Euclidean standards, of course). Other instances are offered in Propositions 4.4 and 4.5.
We next turn to some uniform wedges. Let $D_n(r)$ denote the lamina consisting of the subset

$$\{(\rho, \theta) \in D_n(r) \mid \frac{-\pi}{n} \leq \theta \leq \frac{\pi}{n}\}$$

of the disk $D(r)$ with uniform density 1 (Fig. 3). Let $d_n(r)$ denote the distance from the origin $O$ to $C(D_n(r))$ and let $R = R_{O,2\pi/n}$ denote the counterclockwise rotation by the angle $2\pi/n$ about $O$.

**Proposition 4.3** For the uniform wedge $D_n(r)$

$$\tanh d_n(r) = \frac{n}{\pi} \sin \left(\frac{\pi}{n}\right) \frac{\sinh 2r - 2r}{\cosh 2r - 1}$$

and

$$\text{mass}(D_n(r)) = \frac{\pi \sinh^2 r}{n \cosh d_n(r)}$$

**PROOF:** We abbreviate $D_n(r)$ and $d_n(r)$ to $D_n$ and $d_n$, respectively. By symmetry, Proposition 3.4, and the Law of Cosines

$$\pi \sinh^2 r = \text{mass}(D(r)) = \sum_{i=1}^{n} \text{mass}(R_i(D)) \cosh d_n = n \text{mass}(D_n) \cosh d_n$$

(4)

$$= n \cosh d_n \int_{-\pi/n}^{\pi/n} \int_{0}^{r} \cosh[d(C(D_n), X)] \sinh \rho d\rho d\theta$$

$$= n \cosh d_n \int_{-\pi/n}^{\pi/n} \int_{0}^{r} (\cosh d_n \cosh \rho - \cos \theta \sinh d_n \sinh \rho) \sinh \rho d\rho d\theta$$

$$= n \cosh^2 d_n \int_{-\pi/n}^{\pi/n} \int_{0}^{r} \cosh \rho \sinh \rho d\rho d\theta$$

9
\[
-n \cosh d_n \sinh d_n \int_{-\pi/n}^{\pi/n} \int_0^r \cos \theta \sinh^2 \rho d\rho d\theta
= \cosh^2 d_n \pi \sinh^2 r - n \cosh d_n \sinh d_n \cdot 2 \sin \frac{\pi}{n} \int_0^r \frac{\cosh 2\rho - 1}{2} d\rho
= \pi \cosh^2 d_n \sinh^2 r - n \sinh d_n \cosh d_n \sin \frac{\pi}{n} \left( \frac{\sinh 2r}{2} - r \right).
\]
Division by \( \pi \sinh^2 r \) yields
\[
1 = \cosh^2 d_n - \frac{n}{\pi} \sin \frac{\pi}{n} \sinh d_n \cosh d_n \frac{\sinh 2r - 2r}{\cosh 2r - 1}
\]
or
\[
\sinh^2 d_n = \frac{n}{\pi} \sin \frac{\pi}{n} \sinh d_n \cosh d_n \frac{\sinh 2r - 2r}{\cosh 2r - 1}
\]
or
\[
\tanh d_n = \frac{n}{\pi} \sin \left( \frac{\pi}{n} \right) \frac{\sinh 2r - 2r}{\cosh 2r - 1}.
\]
It follows from Eq’n (4) that
\[
\text{mass}(D_n) = \frac{\pi \sinh^2 r}{n \cosh d_n}
\]
from which is obtained
\[
\text{mass}(D_n(r)) = \frac{\pi \sinh^2 r}{n} \sqrt{1 - \left[ \frac{n}{\pi} \sin \left( \frac{\pi}{n} \right) \frac{\sinh 2r - 2r}{\cosh 2r - 1} \right]^2}.
\]
Q.E.D.

Note that by the proposition above
\[
\frac{d_n}{r} = \frac{n}{\pi} \sin \left( \frac{\pi}{n} \right) \left( \frac{2}{3} + O(r^2) \right)
\]
in comparison to the Euclidean analog of
\[
\frac{2n}{3\pi} \sin \left( \frac{\pi}{n} \right).
\]

We turn next to some polygons. In both the statement and the proof below, the index \( i \) is computed modulo 3.

**Proposition 4.4** Let \( \Delta X_1X_2X_3 \) be a triangular lamina with uniform density \( \lambda \) and let \( O \) be a point in its interior. Then
\[
\text{mass}(\Delta X_1X_2X_3) = \frac{\lambda}{2} \sum_{i=1}^{3} \sinh[(d(O, X_iX_{i+1})]d(X_i, X_{i+1}).
\]
PROOF: To find the mass of the triangle we may assume that the point $O$ is the origin of a Gaussian parametrization of the hyperbolic plane (Fig. 4). Then

$$\text{mass}(\Delta X_1 X_2 X_3) = \lambda \int \int_{\Delta X_1 X_2 X_3} \cosh \rho dA$$

$$= \lambda \sum_{i=1}^{3} \int \int_{\Delta OX_i, X_{i+1}} \cosh \rho dA.$$

Let

$$\rho_i = \rho_i(\theta) = \coth^{-1} \left( C_i \cos(\theta - \alpha_i) \right)$$

be the equation of the geodesic joining $X_{i+1}$ and $X_{i+2}$. If, for $i = 1, 2, 3$, $\theta_i$ is the angle from the horizontal axis to the geodesic $OX_i$ then

$$\int \int_{\Delta OX_i, X_{i+1}} \cosh \rho dA = \int_{\theta_i}^{\theta_{i+1}} \int_{0}^{\rho_{i+2}(\theta)} \cosh \rho \sinh \rho d\rho d\theta$$

$$= \frac{1}{2} \int_{\theta_i}^{\theta_{i+1}} \sinh^2 \rho_i d\theta$$

$$= \frac{1}{2} \int_{\theta_i}^{\theta_{i+1}} \sinh[(\coth^{-1}(C_{i+2} \cos(\theta - \alpha_{i+2})))]^2 d\theta$$

$$= \frac{1}{2} \int_{\theta_i}^{\theta_{i+1}} \frac{d\theta}{C_{i+2}^2 \cos^2(\theta - \alpha_{i+2}) - 1}.$$
On the other hand, the length of the geodesic segment joining $X_iX_{i+1}$ is
\[
d(X_i, X_{i+1}) = \int_{\theta_i}^{\theta_{i+1}} \sqrt{d^2_{i+2} + \sinh^2 \rho_{i+2} d\theta^2}
\]
\[
= \int_{\theta_i}^{\theta_{i+1}} \sqrt{\frac{C_{i+2}^2 \sin^2(\theta - \alpha_{i+2})}{(C_{i+2}^2 \cos^2(\theta - \alpha_{i+2}) - 1)^2} + \frac{1}{C_{i+2}^2 \cos^2(\theta - \alpha_{i+2}) - 1}} d\theta
\]
\[
= \sqrt{C_{i+2}^2 - 1} \int_{\theta_i}^{\theta_{i+1}} \frac{d\theta}{C_{i+2}^2 \cos^2(\theta - \alpha_{i+2}) - 1}
\]
\[
= \sqrt{C_{i+2}^2 - 1} \int \int_{\Delta OX_iX_{i+1}} \cosh \rho dA
\]
Set $d_i = d(O, X_{i+1}X_{i+2})$. Then
\[
\sqrt{C_i^2 - 1} = \sqrt{\coth^2 d_i - 1} = \operatorname{csch} d_i
\]
Hence,
\[
\int \int_{\Delta OX_iX_{i+1}} \cosh \rho dA = \frac{\sinh d_{i+2}}{2} d(X_i, X_{i+1})
\]
and the proposition now follows immediately. Q.E.D.

Note that the formula of the proposition above has a Euclidean analog, namely,
\[
\text{mass}(\Delta X_1X_2X_3) = \frac{\lambda}{2} \sum_{i=1}^{3} d(O, X_iX_{i+1})d(X_i, X_{i+1}).
\]
where $O$ is any point in the interior of the triangle and $d$ denotes Euclidean distance.

The same technique can also be used to prove another formula whose Euclidean analog is also well known.

**Proposition 4.5** The mass of the regular $n$-gon of in-radius $r$ and uniform density $1$ is half the product of its perimeter with sinh $r$.

**PROOF:** Once again we work in the Gauss model of the hyperbolic plane. Set $C = \coth r$ and let $a$ be the hyperbolic length of one of the polygon’s sides (see Fig. 5). Then one side of the polygon is parametrized as
\[
\rho = \coth^{-1}(C \cos \theta), \quad -\pi/n \leq \theta \leq \pi/n.
\]
It follows from the symmetry of the polygon that its mass equals
\[
2n \int_0^{\pi/n} \int_0^{\coth^{-1}(C \cos \theta)} \cosh \rho \sinh \rho d\rho d\theta
\]
Figure 5:

$$= n \int_{0}^{\pi/n} \left[ \sinh(\coth^{-1}(C \cos \theta)) \right]^2 d\theta$$

$$= n \int_{0}^{\pi/n} \left[ \frac{\sqrt{C \cos \theta + 1}}{C \cos \theta - 1} - \frac{\sqrt{C \cos \theta - 1}}{C \cos \theta + 1} \right]^2 d\theta$$

$$= n \int_{0}^{\pi/n} \frac{d\theta}{C^2 \cos^2 \theta - 1} = \frac{n}{\sqrt{C^2 - 1}} \tanh^{-1} \left[ \frac{\tan(\pi/n)}{\sqrt{C^2 - 1}} \right]$$

$$= n \sinh r \tanh^{-1} [\tan(\pi/n) \sinh r]$$

$$= n \sinh r \tanh^{-1} \left[ \tanh \left( \frac{a}{2} \right) \right] = \frac{na \sinh r}{2}.$$  

Q.E.D.

The area of the above regular polygon is well known to be

$$(n - 2)\pi - 2n\beta,$$

where $\beta$ is the angle at its vertices. Thus the mass of the uniform regular polygon is also "better behaved" than its area.

Next, the mass of the uniform triangle is expressed in terms of its sides, thus obtaining an analog of Heron’s formula for the area of a Euclidean triangle.

**Lemma 4.6** Let $ABC$ be a hyperbolic triangle whose medians $AP$, $BQ$, $CR$ intersect at $O$. Then

$$\frac{\sinh AO}{\sinh OP} = \frac{\sinh BO}{\sinh OQ} = \frac{\sinh CO}{\sinh OR} = \delta$$

where

$$\delta^2 = 3 + 2 \cosh a + 2 \cosh b + 2 \cosh c$$
PROOF: Let \( p = d(A, P), p_1 = d(O, P) \) (Fig. 6). By the Hyperbolic Law of Cosines,

\[
\cos \angle APB = \frac{\cosh p \cosh \frac{a}{2} - \cosh b}{\sinh p \sinh \frac{a}{2}}
\]

and

\[
\cos \angle APC = \frac{\cosh p \cosh \frac{a}{2} - \cosh c}{\sinh p \sinh \frac{a}{2}}.
\]

From the addition of these formulas we obtain

\[
2 \cosh p \cosh \frac{a}{2} = \cosh b + \cosh c.
\]

An application of the unsigned Theorem of Menelaus to \( \triangle ACR \) and transversal \( BOQ \) yields

\[
\frac{\sinh \frac{b}{2} \sinh\frac{a}{2}}{\sinh \frac{b}{2} \sinh\frac{a}{2}} \frac{\sinh p_1}{\sinh p_2} = 1
\]

from which it follows that

\[
\frac{\sinh p_2}{\sinh p_1} = \frac{\sinh a}{\sinh \frac{a}{2}} = 2 \cosh \frac{a}{2}.
\]

Hence,

\[
2 \cosh \frac{a}{2} = \frac{\sinh(p - p_1)}{\sinh p_1} = \sinh p \coth p_1 - \cosh p
\]

and

\[
\coth p_1 = \frac{\cosh p + 2 \cosh \frac{a}{2}}{\sinh p}
\]

\[
\frac{1}{\sinh^2 p_1} = \left( \frac{\cosh p + 2 \cosh \frac{a}{2}}{\sinh p} \right)^2 - 1
\]

Therefore

\[
\frac{\sinh^2 p}{\sinh^2 p_1} = (\cosh p + 2 \cosh \frac{a}{2})^2 - \sinh^2 p
\]
\[ 1 + 4 \cosh p \cosh a/2 + 4 \cosh^2 a/2 \]
\[ = 1 + 2 \cosh b + 2 \cosh c + 4 \frac{\cosh a + 1}{2} \]
\[ = 3 + 2 \cosh a + 2 \cosh b + 2 \cosh c. \]
Q.E.D.

**Theorem 4.7** Let the homogeneous hyperbolic \( \triangle ABC \) have constant density \( \lambda \) and set

\[ \Delta = \sqrt{1 - \cosh^2 a - \cosh^2 b - \cosh^2 c + 2 \cosh a \cosh b \cosh c}. \]

and

\[ \delta = \sqrt{3 + 2 \cosh a + 2 \cosh b + 2 \cosh c}. \]

Then

\[ \text{mass}(\triangle ABC) = \frac{\lambda \Delta}{2\delta} \left( \frac{a}{\sinh a} + \frac{b}{\sinh b} + \frac{c}{\sinh c} \right) \]

**PROOF:** Let \( h \) and \( g \) be the hyperbolic distances from \( A \) and \( O \) to \( BC \) (see Fig. 6). By the hyperbolic trigonometry of the right triangle

\[ \frac{\sinh h}{\sinh p} = \sin \angle APB = \frac{\sinh g}{\sinh p_1} \]

so that

\[ \sinh g = \frac{\sinh h}{\delta} = \frac{\sin \beta \sinh c}{\delta} \]

It now follows from Proposition 4.6 that

\[ \text{mass}(\triangle ABC) = \frac{\lambda}{2\delta} (a \sin \beta \sinh c + b \sin \gamma \sinh a + c \sin \alpha \sinh b) \]

and so, by the hyperbolic Law of Sines

\[ \text{mass}(\triangle ABC) = \frac{\lambda}{2\delta} \left( \frac{a}{\sinh a} + \frac{b}{\sinh b} + \frac{c}{\sinh c} \right) \Delta. \]

Q.E.D.

Perron proved that the triangle of Theorem 4.7 has mass

\[ \frac{\lambda}{2} \sqrt{2bc \cos \alpha + 2ca \cos \beta + 2ab \cos \gamma - a^2 - b^2 - c^2} \]

but suggested that it would be of interest to obtain a formula with a radicand that is clearly positive. Since the quantity \( \Delta^2 \) is well known to be positive [Stahl2, p. 106], Theorem 4.7 does indeed fulfill Perron’s suggestion. We also note in passing that, as was known to Perron, it follows from the second equation of Theorem 3.1 that the quantity \( \delta \) of Theorem 4.7 is the total mass of the discrete system obtained by placing unit masses at the vertices of \( \triangle ABC \).

It is well known that the hyperbolic areas of triangles are bounded above by \( \pi \). Such is not the case for the hyperbolic mass.

15
Corollary 4.8  There exist hyperbolic triangles of arbitrarily large mass.

PROOF: Let $a = b = c$ go to infinity in the expression derived in Theorem 4.7. Q.E.D.

5  HIGHER DIMENSIONS

The following is the hyperbolic analog of a Theorem of Pappus. It has been generalized by Robert Foote [Foote 2] in the manner of [Foote 1]. Note that the Gaussian metric on $H^3$ is [Ratcliffe, p. 77]

$$ds^2 = d\rho^2 + \sinh^2 \rho \sin^2 \phi d\theta^2 + \sinh^2 \phi d\phi^2$$

with volume element

$$dV = \sinh^2 \rho \sin \phi d\rho d\theta d\phi$$

Theorem 5.1  In hyperbolic space, let $D$ be the solid formed by rotating a planar region $S$ about an axis $m$ that does not intersect $S$, and let $R$ denote the distance from the center of mass of $S$ to $m$. Then the volume of $D$ equals the product of the 2-dimensional mass of $S$ by the distance traveled by $S'$s center of mass.

PROOF: Let $O$ be the foot of the perpendicular from $S'$s centroid $C$ to the axis $m$. If $P$ is an arbitrary point of $S$, let its polar coordinates be $(\rho, \phi)$ and $(r, \tau)$ as indicated in Figure 7. Finally, let $n$ be a straight line perpendicular to $OC$ at $C$. 

Figure 7:
By the Law of Sines
\[ \sinh \rho \sin \phi = \sinh r \sin \tau \]
and hence
\[ \cosh \rho \sin \phi d\rho + \sinh \rho \cos \phi d\phi = \cosh r \sin \tau dr + \sinh r \cos \tau d\tau. \quad (5) \]

By the Law of Cosines
\[ \cosh \rho = \cosh R \cosh r + \cos \tau \sinh R \sinh r \]
and hence
\[ \sinh \rho d\rho = (\cosh R \sinh r + \cos \tau \sinh R \cosh r)dr - \sin \tau \sinh R \sinh r d\tau. \quad (6) \]

When the wedge product of Eq’ns 5 and 6 is taken, we obtain
\[
\sinh^2 \rho \cos \phi d\phi \wedge d\rho
\]
\[
= (\cosh R \sinh^2 r \cos \tau + \cos^2 \tau \sinh r \cosh r \sinh R) d\tau \wedge dr
\]
\[
- \sin^2 \tau \sinh R \sinh r \cosh r dr \wedge d\tau
\]
\[
= (\cosh R \sinh^2 r \cos \tau + \sinh r \cosh r \sinh R) d\tau \wedge dr.
\]

Consequently
\[
\text{vol}(D) = \iiint_D \sinh^2 \rho \cos \phi d\phi \wedge d\rho \wedge d\theta
\]
\[
= 2\pi \iint_S \sinh^2 \rho \cos \phi d\phi \wedge d\rho
\]
\[
= 2\pi \cosh R \iint_S \sinh^2 r \cos \tau d\tau \wedge dr
\]
\[
+ 2\pi \sinh R \iint_S \sinh r \cosh rd\tau \wedge dr
\]
\[
= 2\pi \cosh R \iiint_S \sinh^2 r \sin(\pi/2 - \tau) d\tau \wedge dr + 2\pi \sinh R \cdot \text{mass}(S)
\]
\[
= 2\pi \cosh R \int_S \sinh dsin \tau d\tau \wedge dr + 2\pi \sinh R \cdot \text{mass}(S)
\]
\[
= 2\pi \cosh R \cdot M_n(S) + 2\pi \sinh R \cdot \text{mass}(S)
\]
\[
= 2\pi \cosh R \cdot 0 + 2\pi \sinh R \cdot \text{mass}(S)
\]
It follows that
\[ \text{vol}(D) = 2\pi \sinh R \cdot \text{mass}(S). \]

Q.E.D.

An \textit{n-simplex} of \( H^n \) is a set of \( n+1 \) points (vertices) \( \sigma = \{ A_0, A_1, ..., A_n \} \) that are not contained in any \( n-1 \) dimensional hyperplane. The convex hull of \( \sigma \) is the \textit{solid simplex} denoted by \( |\sigma| \). A \textit{facet} \( \sigma^i \) of \( \sigma \) is the \( (n-1) \)-simplex obtained by deleting \( A_i \) from \( \sigma \). A \textit{cevian} of a simplex is a line segment that joins a vertex to some point in its opposite facet. The Euclidean version of the following theorem was proved in [Landy].

\textbf{Theorem 5.2} A set \( \{ A_0B_0, A_1B_1, ..., A_nB_n \} \) of cevians of the simplex \( \sigma = \{ A_0, A_1, ..., A_n \} \) in \( H^n \) is concurrent if and only for each \( k = 0, 1, ..., n \) the vertex \( A_k \) can be assigned a weight so that the centroid of each weighted facet is located at \( B_k \).

PROOF: Suppose first that for each \( k = 0, 1, ..., n \), the vertex \( A_k \) has been assigned a weight \( a_k \) so that the centroid of the opposite facet is \( (B_k, b_k) \). Then the centroid of the weighted \( \sigma \) lies on each line segment \( A_kB_k \) and so the cevians in question are concurrent.

The converse is proved by induction on \( n \). The cases \( n = 1, 2 \) are immediate. The case \( n = 2 \) follows easily from the Theorem of Ceva. Assume the theorem holds for all simplices of dimension \( n-2 \), where \( n \geq 3 \). Suppose the cevians \( A_iB_i, i = 0, 1, 2, ..., n \), are concurrent at \( X \). Since the straight lines \( A_0B_0 \) and \( A_1B_1 \) intersect at \( X \) they span a plane, say \( \alpha \). Let \( \sigma \) be the simplex \( \{ A_2, A_3, ..., A_n \} \). We now show that both \( A_0B_1 \) and \( A_1B_0 \) intersect \( |\sigma| \) in the same point.
Note that both straight lines contain points not in the subspace spanned by $\sigma$ and hence, by Pasch’s postulate, each intersects $|\sigma|$ in exactly one point, which points are necessarily in $\alpha \cap |\sigma|$ (See Fig. 8). If the two intersection points were distinct, then $\alpha \cap |\sigma|$, being convex, would be a line segment, thus implying that $\alpha$ and $|\sigma|$ would span an $(n-1)$-dimensional subspace of $H^n$ and contradicting the fact that $\{A_0, A_1, \ldots, A_n\}$ is a simplex. Hence we conclude that there is a point $F$ such that

$$A_0B_1 \cap A_1B_0 \cap |\sigma| = \{F\}.$$  

Let the vertices $A_2, A_3, \ldots, A_n$ of $\sigma$ be assigned the respective weights $\lambda_2, \lambda_3, \ldots, \lambda_n$ so that their centroid is $(F, \lambda_{01})$, for some real number $\lambda_{01}$. Let $\lambda_0, \lambda_1$ be weights such that

$$C(\{(A_0, \lambda_0), (A_2, \lambda_2), \ldots, (A_n, \lambda_n)\}) = C(\{(A_0, \lambda_0), (F, \lambda_{01})\}) = (B_1, \ldots)$$

and

$$C(\{(A_1, \lambda_1), (A_2, \lambda_2), \ldots, (A_n, \lambda_n)\}) = C(\{(A_1, \lambda_1), (F, \lambda_{01})\}) = (B_0, \ldots)$$

Then, by Prop’n 3.3,

$$C(\{(A_0, \lambda_0), (A_1, \lambda_1), \ldots, (A_n, \lambda_n)\}) = C(\{(A_0, \lambda_0), (A_1, \lambda_1), (F, \lambda_{01})\}) = (X, \ldots)$$

Q.E.D.

### 6 Formulas of the Hyperbolic Triangle

**Theorem 6.1** Let $\triangle ABC$ be the hyperbolic triangle of Figure 9 and set

$$\Delta = \sqrt{1 - \cosh^2 a - \cosh^2 b - \cosh^2 c + 2 \cosh a \cosh b \cosh c}$$
Then
\[
\frac{\sinh a}{\sin \alpha} = \frac{\sinh b}{\sin \beta} = \frac{\sinh c}{\sin \gamma} = \frac{\Delta}{\sinh a \sinh b \sinh c} \quad \text{(Law of Sines)}
\]
\[
\cosh a = \cosh b \cosh c - \cos \alpha \sinh b \sinh c \quad \text{(Law of Cosines)}
\]

**Theorem 6.2** Let \(P, Q, R\), be points on the respective extended sides \(AB, BC, AC\) of the hyperbolic \(\triangle ABC\). Then

**Theorem of Ceva:**
\[
AP, BQ, CR \text{ are concurrent if and only if }
\]
\[
\frac{\sinh AR \sinh BP \sinh CQ}{\sinh RB \sinh PC \sinh QA} = 1;
\]

**Theorem of Menelaus:**
\[
P, Q, R \text{ are collinear if and only if }
\]
\[
\frac{\sinh AR \sinh BP \sinh CQ}{\sinh RB \sinh PC \sinh QA} = -1.
\]
